At Memphis Zoo, Steven Reichling has embarked on a long-term study of the Louisiana Pine Snake (*Pituophis melanoleucus ruthveni*) (1986, 1988a, 1989, 1990a, 1990b, 2008) and the Black Pine Snake (*P. m. lodingi*) in 1981—both taxa are at risk. At Cheyenne Mountain Zoological Park, Connors (1986) described a captive breeding of the Great Basin Gopher Snake (*P. catenifer deserticola*). Charles Shaw and Sheldon Campbell from San Diego Zoo described male combat, courtship behavior and reproduction, feeding, defense, and many other aspects of the Gopher Snake (*Pituophis catenifer*) in their book *Snakes of the American West* (1974, Fig. 11). This is an excellent reference for all the snakes in this area. Shaw (1951) described male combat in American colubrid snakes with remarks on combat in other colubrid and elapid snakes. From the same Zoo, Jeffrey Lemm (2006) has published a field guide to herps of the San Diego region. Chiszar et al. (1989) showed that Bull Snakes (*Pituophis melanoleucus*) discriminated between thermally different rodent carcasses. An adult at Dallas Zoo regularly pinned as many as four live mice at the same time during feeding bouts; the one it was swallowing had been constricted and was dead, the second was being constricted by the first third of the body, the third and fourth were being pressed against the side of the enclosure with such force that they were gasping. I never could answer the question of how a snake could deal with multiple prey items.

At Zoo Atlanta and other institutions, neonates of the Eastern Indigo Snake (*Drymarchon couperi*) were maintained for a captive head-start program (Speake and Smith 1987; Wines 2014). Gravid females were collected in the wild, eggs were hatched, and females released at site of capture. This is an excellent model for a collaborative project; it involved U.S. Fish and Wildlife Service, The Alabama Natural Heritage Program, Alabama Department of Conservation and Natural Resources, Georgia Department of Natural Resources, Zoo Atlanta, The Orianne Society, and the U.S. Forest Service. The researchers examined reproductive ecology, captive propagation, juvenile ecology and restocking potential, including optimal egg incubation temperature, and the effects of diet on growth of hatchlings. After necropsying many indigo snakes, pathologist John Roberts (pers. comm.) was adamant in insisting that these snakes need a predominantly bird diet rather than rodent diet. Serum chemistry values were analyzed for two specimens at Sacramento Zoo (Drew 1994). Hellmuth et al. (2012) used operant conditioning and desensitization to facilitate veterinary care with this taxon at National Zoological Park in Washington, DC. Groves (1960) bred the Eastern Indigo Snake (*D. couperi*) at the Baltimore Zoo.

Some species are rarely kept in zoos and aquariums and thus are poorly studied. There are many reasons why certain taxa do not make their way to zoos and aquariums—availability, specialized food needs, non-attractiveness or other lack of visitor appeal, inability to adapt to captivity, size, secretiveness, poor temperament, lack of managed captive management

FIG. 12. John Anderson published *Zoology of Egypt* in 1898. Some of the finest drawings of reptiles ever produced were by P. J. Smit and John Green in this book. Pictured is Egg-eating Snake *(Dasypeltis scabra).*

program, lack of space and, of course, curatorial preferences. Cahill (1971) provided observations on a captive Beak-Nosed Snake (*Scaphiophis albopunctatus*) at the University of Ife Zoo in Nigeria. Simmons (1977) reproduced the Chinese Red Snake (*Dinodon rufozonatum*) and Campbell and Murphy (1984) outlined reproduction in five species of Paraguayan colubrids housed at the Fort Worth Zoo—racers (*Liophis*), false cobras (*Hydrodynastes*), green racers (*Philodryas*). At Houston Zoo, Freed (1989) documented delayed fertilization in the African Egg-eating Snake (*Dasypeltis scabra*), a species rarely kept in zoos because of the need for a steady supply of suitably-sized eggs (Fig. 12). Shaw (1961) published photographs of an egg-eating snake swallowing an egg. Boycott (1990) described copulation and parturition in the Mole Snake (*Pseudaspis cana*) at Transvaal Snake Park (Fig. 13). Dathe and Dedekind explained care and breeding of Horseshoe Snakes (*Coluber hippocrepis*) (1988), and Madagascar Hog-nosed Snakes (1996) in the Berlin Tierpark. Campbell and Murphy (1977) described reproductive biology of two colubrid snake species from the Malagasy Republic, Madagascar Hog-nosed Snakes *Leioheterodon madagascariensis* and *Madagascariophis colubrina.*

At Dallas Zoo and a few others, the Southern Hognose Snake (*Heterodon simus*) was maintained but the Eastern Hognose Snake (*Heterodon platirhinos*) was rarely exhibited. This was because the former usually fed on rodents whereas the latter almost always restricted its diet to toads or occasionally frogs, difficult to find during winter. In one case, a beautiful orange-phase Eastern Hognose was on display at another facility but the supply of toads disappeared. In desperation, the caretaker offered a large horned frog (*Ceratophrys*). The battle was epic with the frog trying to swallow the snake for many minutes; at the end, the snake prevailed. The South American Hognose Snakes (*Xenodon dorbignyi, X. pulcher*) are now showing up in zoo collections, due to attractive coloring and hardiness in captivity.

One of the most spectacular snakes in our collection at Dallas Zoo was the Filetail Ground Snake (*Sonora aemula*) from northwestern Mexico. Our specimen, about a foot long, had a brilliant red body with a black head and whitish collar. It lived in a gallon jar with a moist paper towel and small water dish and fed on small insects. The snake remained visible most of the time and always caught the eye of our visitors. Many years ago, we held an open-house tour of the reptile building, complete with wine and cheese in the lobby, for an ASIH meeting held in Fort Worth. While we were enjoying the repast, one of our attending herpetological or ichthyological colleagues slipped into the rear section, opened the jar, stole the snake, and replaced the cover—the snake was never recovered.

At Dallas Zoo and Zoo Atlanta where I started my career, we had several snakes with foul tempers. The most notorious were Wagler's Snake (*Xenodon merremi*), Jackson's Twig Snake (*Thrasops jacksoni*), sipo (*Chironius* sp.), Indian Ratsnake (*Ptyas mucosa*), rear-fanged Mangrove Snake (*Boiga dendrophila*), tropical racer (*Masticodryas*), and several US watersnakes (*Nerodia*). Curator Joe Laszlo at San Antonio Zoo had a few examples of keelback snakes, genus *Helicops,* comprising about 16 species. Although small, they were incredibly skillful at biting and left tiny teeth marks. Joe invited visiting herpetologists to touch the tail without being bitten—these snakes swapped ends so quickly that few were able to avoid being bitten even though forewarned. These episodes helped pass the time for us during my visits. I strongly recommend that all of these noxious creatures be excluded from future collection plans.

I have always been intrigued by snake patterns and colors, especially since many from various parts of the world are similar. One of the most striking combinations are a coralsnake-mimic coloring anteriorly and a unicolored part posteriorly in the colubrid Neckband Snake, *Scaphiodontophis annulatus* (Fig. 14). At Dallas Zoo in the 1970s, an adult was obtained which fed well in captivity on a diet of anoles and skinks, which were swallowed alive at astounding speed. The snake often rested

FIG. 14. *Mesopeltis dimidiatus* (above) and *Henicognathus venustissimus* from *Biologia Centrali Americana: Reptilia and Batrachia* in 1885–1902 by Albert Günther. *Henicognathus* is now *Scaphiodontophis*; the congener *S. annulatus* (Neckband Snake) was maintained at Dallas Zoo.

with the anterior portion of the body elevated. I decided to test the snake's reactions to potential predators or their scents—European Ferret, Gray Fox, skunk, raptor feathers, and humans. The snake remained motionless rather than thrashing the body as was described in a paper by Henderson (1984). The tail of this species is exceedingly long and breaks easily (likely in response to predators) but this did not happen in our specimen.

Coachwhips (*Coluber flagellum*) and Racers (*C. constrictor*) are rarely kept in zoo collections as they are snappy, nervous, and flighty. In fact, an adult male Racer was the only snake in my career to have aggressively attacked me without provocation. I encountered this male courting a female in the wild during high school and this suitor likely wanted privacy. I retreated and the snake continued to pursue me, wildly striking.

During my college years, I had a perverse streak which, some would say, lasts even to this day. I had captured an adult black-phase Coachwhip in Florida. For my speech class, I gave a riveting presentation in dulcet tones on snakes, using some of my calm live captives as examples. Admittedly, many of the students were apprehensive but fascinated. I finished by talking about the exceptional speed, aggressiveness, and toxicity of black mambas and slowly opened the cloth bag containing my black-phase Coachwhip, which promptly exploded from the bag and shot off the stage into the crowd. There was complete pandemonium as the students rushed toward the exits, scattering chairs in their way—within minutes, I was standing alone in the room. The professor, who bolted as well and peeked around the open door frame to see if the snake had been secured, thought it was hilarious and gave me an A+ for the class. He said that it was one of the few presentations that was not dreadfully boring!

Husbandry and Medical Management

In my earlier papers and books, I listed many titles dealing with these subjects. There is a comprehensive new book that must be on the bookshelf of every person maintaining live herpetofauna—Petzold's *The Lives of Captive Reptiles*. This wonderful compilation, translated into English by Heichler and Murphy (2008), includes aspects of reproduction, development, nutrition, history of zoos, relevance of terrarium observations, and conservation programs in zoos and private terraria. See Peeling's review (2009) for details.

Campden-Main from the Louisiana Purchase Zoo in Monroe wrote a paper on the care of newborn snakes (Campden-Main and Campden-Main 1982). Banks (1985) observed feeding and sloughing in a collection of captive snakes. Greene (1983) collected data from a number of serpents in zoos to strengthen his analysis of the dietary correlates of the origin and radiation of snakes. These data are helpful when considering suitable prey items. Bloxam and Tonge (1986) appraised the breeding program for reptiles at the Jersey Zoo. William Gehrmann discussed lighting requirements in several papers (1971, 1987, 1994). Murphy and Campbell (1987a) provided selected references applicable to the maintenance of snakes in captivity and a book chapter on captive maintenance the same year (Murphy and Campbell 1987b).

Susan Barnard from Zoo Atlanta and her associates have published a number of papers on parasitism in snakes. Camin and associates (1948, 1953, 1964) documented the ravages caused by the snake mite (*Ophionyssus natricis*) in captive reptile collections. Da Paixão Sevá et al. (2011) described occurrence and molecular diagnosis of *Cryptosporidium serpentis* in captive kingsnakes and ratsnakes in São Paulo, Brazil.

Lloyd at the Roger Williams Park Zoo in Rhode Island published three papers on ophidian paramyxovirus and reptilian dystocias (Lloyd and Flanagan 1991; Lloyd 1990, 1992). Reichling (1988b) discussed treatment of dystocia in snakes. Ungureanu et al. (1972) identified hemorrhagic septicemia in snakes in captivity at Zoological Garden of Bucharest. At Philadelphia Zoo, Aronson (1929) described spontaneous tuberculosis (*Mycobacterium thamnopheos*) in garter snakes. Adamy (1966) investigated the therapy of salmonellosis. Mitch Bush and associates from the Smithsonian National Zoological Park published papers on the use of antibiotics in snakes (1976), biological half-life of Gentamicin in Gopher Snakes (1978), and blood collection and injection techniques in snakes (1978). At the same zoo, Nichols and Lamirande (1994) used methohexital sodium as an anesthetic for colubrid snakes. Hilf et al. (1989) investigated pharmacokinetics of Gentamicin and Piperacillin in blood pythons and Hilf et al. (1990) did a comparative study of upper airway flora in healthy boid snakes and snakes with pneumonia at Pittsburgh Zoo. Velayan and Ambu (1991) studied bacterial infections in reptiles at the National Zoo, Malaysia. Flanagan and Harwell (1983) from Houston Zoo discussed pathobiology and management of chronic regurgitation in snakes. At Baltimore Zoo, Cranfield and Graczyk (1995) expanded information on ophidian cryptosporidiosis. Ippen (1980) described mycosis in snakes. Garner et

al. (1995) diagnosed vertebral chondrosarcoma in a Corn Snake (*Pantherophis guttatus*). Zachiesche et al. (1988) diagnosed lymphoid leukemia with presence of type C virus particles in a Yellow Ratsnake (*P. obsoletus*).

A Few Snake Families Rarely Kept in Zoos

Acrochordidae—Dunn et al. (1987) were successful in exhibiting and breeding the Arafura File Snake *(Acrochordus arafurae*) at Melbourne Zoo. Banks (1989) described skin lesions in *Acrochordus* and *Erpeton,* perhaps caused by excessively bright lighting. Our captives did not have skin lesions, which may be due in part to the presence of aquatic snails in their aquaria or relatively high pH (above 7.2). The snails were often on the heads and bodies of the snakes; algae growth did not occur and there were no shedding problems including eye caps. Curator Louis Pistoia told me that an adult Java Wart Snake (*A. javanicus*) refused food for slightly over four years in the Columbus Zoo collection. Dowling (1960) described feeding habits at Bronx Zoo. In the 1970s, *A. javanicus* was imported in small numbers to the US. The snakes were poor feeders on living fishes at Dallas Zoo until the water temperature was raised to 85°F (30°C) or slightly higher. Dubach et al. (1997) described parthenogenesis in the Arafura File Snake at Chicago Zoological Park.

Aniliidae—The only living zoo examples of Coral Cylinder Snake (*Anilius scytale*) I have seen were a few in collections in South America. This is likely due to specialized dietary requirements: amphisbaenians, caecilians, and snakes. Defensive tail display has been observed at Instituto Butantan (Sawaya 2010, Fig. 15).

Cylindrophiidae—The only living representatives of this group I have seen in zoo collections were a few Red-tailed Pipe Snakes (*Cylindrophis ruffus*) years ago at the Oklahoma City Zoo (Fig. 16). When I asked if the snakes ever displayed the characteristic tail-raising defensive behavior, the caretakers said that the snakes did briefly at first but quickly habituated to captivity.

Leptotyphlopidae—The only living example during my early career was a large snake called Giant Blind Snake (*Leptotyphlops maximus*) from Mexico at Dallas Zoo. The snake had been confiscated by US Fish and Wildlife Service and was given that technical name on the manifest[1]. The feeding behavior corresponded to the description by Kley (2001), known as mandibular raking. Ants, eggs, and larvae were literally sucked up like a vacuum cleaner; I have never seen a snake go into a feeding frenzy quite like this. In the beginning, we fed this snake Carpenter ants collected from nests on Zoo grounds. When fire ants arrived in Dallas, all carpenter ants disappeared and we were unable to find some to feed the snake. In desperation, I tried to collect fire ants to substitute but I regretted that plan immediately after multiple encounters with their defensive behavior. When I offered them to the snake, known as an ant specialist, it immediately went into convulsions. Amazingly, the ants had penetrated the interstitial skin between the scales and

[1]In this shipment, approximately 2000 tarantulas, each in its own small plastic bag, were included. Most were the Red-legged Tarantula but several other types were present as well. The wildlife inspector was worried that the arachnids would dehydrate and suffocate so he asked me to help him transfer the animals to larger containers with air holes and include a damp paper towel for moisture. One of the primary defenses is to flick urticating hairs (bristles), which are extremely irritating, especially to those persons with severe allergies. We had several tarantulas in the Dallas Zoo collection that I handled for demonstrations with no negative reactions but, as these tarantulas were unpacked, the hairs literally coated the room and after several hours of handling the creatures, my whole body began to itch and the result was excruciating. For two days, I soaked in the bathtub at home with Epsom salts added to the water to lessen the pain and diminish swelling, cursing the inspector who seemed to have no negative reaction and was amused by my plight. When I called in sick to the Zoo to explain the circumstances, my boss was quite skeptical. All of the confiscated tarantulas were donated to a university researcher a few days later. Also in this shipment were about three dozen adult spiny-tailed iguanas (*Ctenosaura pectinata* and *C. similis*). We did not have suitable holding space in the reptile building so the lizards were released in the rear section of the spacious aquarium, an antiquated Art Deco concrete structure in Fair Park. They immediately scaled the rough concrete walls and ran around the wide tops of the large cement aquaria, often basking under the display lights. We fed them several times a week and they would descend like ravenous wolves from all directions and snatch vegetables and dog food from the metal trays placed on the floor. They lived for years but avoided the water in the tanks, unlike Green Iguanas, which dive into water to escape predators.

FIG. 18. Title page from *Promenade au jardin zoologique d'Anvers par Eugéne Gens* by Eugéne Gens in 1861.

were attached to the snake's body. I immediately put the snake under running water and eventually the ants released their grip. Later, the snake laid three infertile eggs but did not coil around the clutch as mentioned in the literature about some blindsnakes.

Typhlopidae—I have never seen an exhibit of blind snakes (scolecophidians) in a zoo. These snakes are the most basal form for a visitor to compare against advanced snakes (caenophidians), but absence from collections is almost certainly due to difficulty in finding enough food throughout the year and the secretive nature of the animals. We found what we believed to be an adult Flowerpot Snake *Rhamphotyphlops* (now *Indotyphlops*) *braminus* in a pile of mulch outside the back door of the reptile building at the National Zoological Park in Washington DC. I asked the horticulturist who had delivered the pile and she said that the material had been ground into small pieces from branches trimmed from a standing dead tree on Zoo property and almost immediately brought to the building in the bed of a pickup truck. It may have traveled from flower pots delivered to the Zoo but she did not believe that this was the case as there were no pots anywhere near the tree. This invasive species is known from Massachusetts and Florida. My plan was to preserve the snake as a voucher specimen for certain identification but it wriggled through my fingers and catapulted into the adjacent outdoor alligator exhibit, never to be seen again.

Uropeltidae—In the April 2011 issue of Zoo's Print, the magazine of the Zoo Outreach Organization, the list of reptiles assessed during the Conservation Assessment and Management Plan (CAMP) workshop in Western Ghats, India in March 2011 included 20 species of shield-tail snakes (*Uropeltis*). The collected data are being analyzed to determine the conservation needs for reptiles throughout India and will be published in a future IUCN Red List.

Xenopeltidae—McGeorge (1997) bred the Sunbeam Snake *(Xenopeltis unicolor)* at Chester Zoo.

SUMMARY

During the past few decades, there has been an increasingly vocal group of animal rights advocates calling for a ban against keeping live animals in captivity. They claim that animal welfare issues are ignored and the captives live unenriched and unfulfilled lives. Concurrently, there have been objections to collecting and euthanizing animals for scientific research collections. Both of these views are misguided, for if this happened we would not be able to add very much to our current understanding of snake biology.

In reading my four-part series on snakes kept in zoos and aquariums through centuries (Murphy 2014a, b, c; this paper), it should be apparent that many important scientific studies have been generated and replicated in that environment. In fact, many of the questions posed could not have been investigated in the wild. For example, how would we have known that some pythons incubate egg clutches to increase temperatures by twitching? What behaviors are apparent when males court females? What are the communication channels? Which snakes lay eggs and which ones give birth to living young? Does parthenogenesis happen?

What do hemipenes look like and how do they work? Former curator Herndon Dowling at New York Zoological Society published several important studies on the morphology of these structures (1959b, 1959c, 1967; Dowling and Savage 1960). Observations on living Ottoman Vipers (*Vipera xanthina*) at Dallas Zoo documented usage (Murphy and Barker 1980). Dowling also published a paper on zoo record-keeping (Dowling and Gilboa 1966), a critical component for documenting interesting animals doing interesting things.

Because snakes are essentially living tubes without limbs, how do they move and how do snakes find and dispatch their prey? Or swallow prey much larger than themselves? Being ectothermic, how can they digest meals and live and prosper in a world of changing climatic conditions? Several researchers

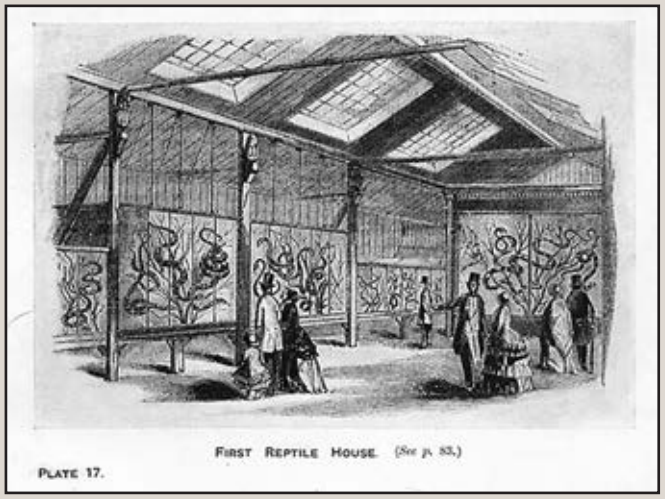

FIG. 19. Illustration of London Zoo reptile building. The beginning of an article from *The Illustrated London News* on 2 June 1849 reads as follows: "The new reptile house in the Gardens of the Zoological Society in the Regent's Park will ultimately form one of the most instructive, as it is the most novel and original feature in this delightful institution. The collection already contained in it is so unexpectedly brilliant, considering the small number of reptiles previously exhibited in the Menagerie, that we cannot but anticipate the most important results in the study of this singularly interesting division of the animal kingdom."

COURTESY OF ROBERT MENDYK

FIG. 20. How did this keeper feed these snakes (probably Reticulated Pythons, *Malayopython reticulatus*) in the same enclosure without them grabing and constricting each other? Possibly that is the reason he is holding a broom. Illustration called "The Meal of Serpents in Museum d' histoire Naturelle" from *Magasin pittoresque* to the 56th année, sér. II, tome VI, p. 241, 1888. The Menagerie Jardin des Plantes is part of the museum, located in Paris (see Murphy 2009a, b for history).

have published important studies that should be consulted: David Chiszar, David Cundall, Alexandra Duefel, Carl Gans, Frances Irish, Ken Kardong, Hamidreza Marvi and associates at Zoo Atlanta, Hobart Smith, Steve Secor, and others.

How can some live underground, others above ground, some in water, and others high in trees? What structural modifications are needed to do this? Harvey Lillywhite (2014) tells us how.

How do serpents defend themselves against predators (Greene 1997)? And against humans who want to chop them into tiny bits? Since human ophiophobia is a real phenomenon (Burghardt et al. 2009), why do we so-called intelligent beings want to wear their skins if ophidians frighten us and many are collected in unsustainable numbers for the fashion industry? When I ask some visitors and acquaintances who hate and fear snakes and other reptiles why they are wearing cobra shoes, python handbags, lizard hatbands, croc wallets and belts, and other reptilian accoutrements, they are clueless and find my question irrelevant and/or offensive. When I say that the fashion industry is responsible for millions of reptile deaths annually, there exists an enormous illegal black market worldwide, reptiles may be brutally dispatched by being skinned alive but cannot scream in pain, and many populations are seriously endangered, they often are completely indifferent. When I suggest that it would be interesting to study these fashion statements as possible subliminal expressions of dominance over a fallen enemy, they simply shrug their shoulders and view me as a lunatic. Would natural selection favoring ugly or nondescript skins be an advantage to survival? Probably not as I have seen plenty of artificially-colored reptile skin products in department stores and boutiques and most are garish, offending my aesthetic sense.

Most humans will never encounter a living snake in the wild. So would they miss seeing their stunning beauty and remarkable morphology unless they visited a zoo or aquarium? At the London Zoo, visitors were asked to rank their favorite exhibits; two of the three most popular were the aquarium and reptile house (Balmford et al. 1996; Balmford 2000). The message here is snakes may be fearful and unsettling but humans are fascinated with them nonetheless and a zoo visit must almost always include seeing them. One day outside a zoo reptile building, I sat on a bench next to an older female visitor who was waiting for her family to exit. I asked why she did not go into the place to see the snakes with her relatives as these creatures were well worth seeing. I was told in no uncertain terms that she could not even tolerate listening to the word "snake" much less view serpents. Even seeing a picture of one would send her to the sick bed for several days. Her family's daily task was to review incoming printed materials to intercept any snake images and remove them. Our interaction was quickly finished, especially since I did not feel like calling the paramedic squad that day should she see an ophidian. She was fortunate that I was not wearing my favorite ball python T-shirt showing a wide range of color morphs coiled together.

These are not questions generated by me. Rather, these are some of the intriguing enquiries over the past centuries explored and answered by our predecessors and we owe them a huge debt of gratitude. And it must be remembered that virtually none of this would have happened without zoos, aquariums, academic institutions, and museums (Figs. 17–20).

Acknowledgments.—This contribution is dedicated to Charles C. (Chuck) Carpenter and his then-graduate student James C. Gillingham from University of Oklahoma in Norman. Beginning in 1975,

we began a collaborative effort to study the behaviors of reptiles in the Dallas Zoo collection—two rattlesnake species, Madagascan Tree Boa, Blue-tongue Skink, Angle-headed Dragon, Gillen's Monitor, Death Adder, Fiji Island Iguana, and kingsnakes. About a decade later, Chuck published a paper on dominance of snakes (Carpenter 1984), based in part on observations at Dallas Zoo. We all learned an important lesson as we spent hours trying to document their lives—under carefully controlled conditions, animals tend to do as they damn well please!

For various courtesies, I thank Kraig Adler, Judith Block, Kristen Bullard, John Edwards, Matt Evans, Kevin de Queiroz, Harry Greene, Robert Hansen, William Lamar, Jim Langhammer, Joe Mendelson, Polly Lasker, Roy McDiarmid, Robert Mendyk, Matt Neff, Leslie Overstreet, Ray Pawley, Chad Peeling, Clyde Peeling, and George Zug.

NYASA CROCODILES
Harry Hamilton — original line drawing

Nyasa Crocodiles (*Crocodylus niloticus*). Original line drawing by Harry Hamilton Johnston (12 June 1858–31 July 1927) appearing on page 357 of his 1897 book *British Central Africa. An Attempt to Give Some Account of a Portion of the Territories under British Influence North of the Zambezi River* (Methuen & Co., London). Sir Harry Johnston was a prolific writer and explorer, and a very important figure in Britain's colonial expansion in Africa during the end of the 19th and beginning of the 20th centuries. He studied painting at the Royal Academy, having early shown an interest in drawing and painting birds. He frequented the Zoological Gardens in London and the British Museum (Natural History), and he independently studied zoology at Regent's Park and anatomy at the museum of the Royal College of Surgeons. After several exploring expeditions in Africa from 1879–1884, he entered the British Foreign Office in 1885 and was posted to Cameroon and the Niger River (1886, as Vice Consul, later Consul), Mozambique (1889, as Consul), Nyasaland (= Malawi) (1891, as British Commissioner for South Central Africa), Tunisia (1897, as Consul General), and Uganda (1899, as Special Commissioner). Johnston was a prolific writer, with more than 600 articles and books to his credit, including extensive accounts of African societies, peoples, languages, history, geography, and natural history, particularly in Liberia, Uganda, and Central and East Africa. He used his artistic talents to illustrate his books, and his natural history illustrations are of particularly high quality.

Nyasa Crocodiles is the only herpetological illustration in *British Central Africa*. Johnston traveled widely around Lake Nyasa and noted the abundance of crocodiles there. He was the first explorer to observe that Nile Crocodiles used their legs to rise-up and run awkwardly into the lake rather than slither as was commonly misperceived at the time. *British Central Africa* contains a short narrative of the reptiles, but not amphibians, recorded from the region (pp. 355–359) and an appendix of all species (pp. 361–362; 1 crocodile, 9 chelonians, 18 lizards, 21 snakes, 10 frogs). The narratives include personal observations of Johnston's encounters with reptiles, as well as native stories and anecdotes. More extensive herpetological observations and illustrations were included in Johnston's 1906 book *Liberia* (see Dodd 2014. Bibliotheca Herpetologica 10:33–43).

Submitted by **C. Kenneth Dodd, Jr.**, Department of Wildlife Ecology and Conservation, University of Florida, Gainesville, Florida 32611, USA; e-mail: Terrapene600@gmail.com

ABOUT OUR COVER: *Celestus hylaius*

The 50 species of the lizard family Diploglossidae ("galliwasps") are distributed among three genera—*Celestus*, *Diploglossus*, and *Ophiodes*—with a collective range from Central to South America, including Caribbean islands. These are small to medium-sized lizards, usually found in forested habitats. Closely related to the Anguidae, they share many characteristics such as heavily armored bodies. The genus *Celestus* contains 29 species (Uetz and Hošek [eds.]. The Reptile Database, http://www.reptile-database.org, accessed 18 Oct 2014) of skink-like lizards defined by exposed claws on the digits, enlarged head scales, and other cranial scale features. *Celestus hylaius*, described in 1993 (Savage and Lips 1993. Revista de Biología Tropical 41:817–842), is a rarely encountered lizard of lowland wet and moist forests of the Atlantic versant of Costa Rica, at elevations of 40–403 m (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. University of Chicago Press, Chicago, Illinois. 934 pp.). The individual depicted on our cover was found at an elevation of 700 m in the leaf litter on a trail at Rara Avis Rainforest Lodge and Reserve.

Several specimens of *Celestus hylaius* have been found over the years at Rara Avis during the course of long-running surveys by Twan Leenders and others. Rara Avis Reserve is located on the northeast border of Braulio Carillo National Park, Costa Rica. It is south of the renowned La Selva Biological Station, which is lowland forest. Rara Avis Reserve consists of primary and secondary forest on the slopes of Volcán Barva, with elevations ranging from 600–750 m. Rara Avis contains an amazing diversity of species such as nearly 400 species of birds, at least 46 species of amphibians, and 85 species of reptiles, including undescribed species.

Our cover subject was recorded in March 2010 by **Tim Paine**, using a Nikon D3 with a Nikon 105mm macro lens and two SB800 speedlights in soft boxes at f/22, 1/60s, ISO 200. Tim has made a substantial number of visits to Costa Rica, many working with Twan Leenders. When not engaged in herpetological and photographic pursuits, Tim serves as a police officer with the San Francisco Police Department, where he has worked for nearly 20 years. He travels often to Latin American destinations to photograph herps and is involved with TreeWalkers International and PrimatesPeru, two non-profits dedicated to research, conservation, and education. More of Tim's images and writing can be found at http://amphibios.org.

SSAR BUSINESS

WELCOME LETTER FROM THE NEW SSAR PRESIDENT

AARON M. BAUER

WITH A SPECIAL MESSAGE FOR STUDENTS

PHOTO BY INDRANEIL DAS

Continuing in the tradition of recent past presidents I am pleased to have this opportunity to introduce myself to the SSAR membership and to lay out some of the upcoming opportunities and challenges that our society will be facing in the next few years. I was born in New York City and grew up on nearby Long Island, in Old Westbury and later in Mineola. I was strongly influenced by visits to the American Museum of Natural History and by the age of five had decided that I wanted to be a herpetologist — a decision that was solidified that year when I caught my first Smooth Greensnake (*Opheodrys vernalis*). When searching for universities, I looked for a place that offered undergraduate courses in herpetology and zoogeography and chose Michigan State University. Despite my interest in herpetology I had no idea what I would actually do with amphibians and reptiles, or how one made a living as a herpetologist. At MSU I took classes from two herpetologists, Jim Edwards and the late Max Hensley. In an advanced morphology course I had the opportunity to be the student host for Carl Gans and this helped point me in the direction of an academic career in reptile morphology. At MSU I also indulged my interest in history and did a second major in this field. Although my concentration at the time was in ancient history, I also did research in the history of science.

Largely through the influence of Jim Edwards, I applied to the University of California, Berkeley for doctoral work and was accepted in the lab of Marvalee Wake. At the time there were a record number of "lizard students" in the Museum of Vertebrate Zoology, including Kurt Schwenk, David Good, Kevin de Queiroz, Jonathon Losos, Claudia Luke, Fabian Jaksic, and Jonathon Carothers, who, along with Marvalee and David Wake, Harry Greene and the other students and faculty in the Department of Zoology and the MVZ, made Berkeley an incredibly exciting place to be. It was also a time when phylogenetic systematics was burgeoning and as I

progressed I realized that I needed to work on the systematics of my organisms before I could really interpret their morphology.

My first field trip was to Chiapas, Mexico, where Marvalee sent me to collect caecilians. I think I must be one of the only people whose first 30 field numbers were assigned to gymnophiones. With the help of small grants from the American Museum and the National Academy of Sciences, I made an extensive museum trip across the U.S. and the following year I did the same in Europe, spending three months in collections before carrying on to Australia, New Caledonia, and New Zealand, where I collected specimens for my dissertation on the systematics, evolutionary morphology, and biogeography of carphodactyline geckos (now Carphodactylidae and Diplodactylidae). I made several return trips to the South Pacific, especially to New Caledonia, and I became a true travel junkie.

Following graduation in 1986 I was hired to teach Comparative Vertebrate Anatomy for a semester at Berkeley, which allowed/forced me to develop a set of lectures for the course. I then moved to the University of Calgary for a postdoc with Tony Russell, a leader in the field of lizard morphology, with whom I had already been collaborating throughout my time at Berkeley. While at Calgary I made my first trip to southern Africa and almost my only foray into North American herpetology, publishing the book *The Amphibians and Reptiles of Alberta* with Tony.

In 1988 I moved to Villanova University, just west of Philadelphia, and have been there ever since. Villanova has no doctoral program, but I am the director of our Masters program, which attracts many excellent herpetology students. My current work centers on the phylogenetics, taxonomy, evolutionary morphology and biogeography of geckos, skinks, lacertids, cordylids, gerrhosaurs, and agamids in the Old World. My students and I work extensively in southern Africa (Namibia, South Africa, Angola, Zimbabwe, Botswana, Swaziland, Malawi), the South Pacific (Australia, New Zealand, New Caledonia), and tropical Asia (India, Sri Lanka, Malaysia, Thailand). I also work in the history of herpetology and herpetological collections from the 16th through the 19th centuries.

Professional Service

I have served the herpetological community in a variety of positions. I have served on the Board of Governors of ASIH and on the ASIH Planning and Finance, Nominations, Resolutions, and Honorary Foreign Member Committees. For The Herpetologists' League I served as a Board of Trustees member, president, and chair of the Symposium Committee, and Associate Editor for *Herpetologica*. I have also been chairman of the Herpetological Association of Africa and Secretary General of the World Congress of Herpetology. With respect to SSAR, I have been a member since 1982 and have served on the Resolutions committee, as chair of the Nominating Committee, as Editor of Facsimile Reprints in Herpetology, Book Review Editor for *Herpetological Review*, and as Associate Editor for *Journal of Herpetology*. I believe strongly in playing an active role in the societies to which I belong and encourage my students to do the same. I believe that even beginning students should choose at least one professional society to belong to and become invested: go to the business meeting, volunteer to review manuscripts or serve on committees, spread the word via social media, etc. This is an important part of becoming a professional in our field. It doesn't matter what society one joins, but participate. Student membership costs no more than a nice meal out or a night at the bar!

Challenges

For more than a decade the model of how herpetological societies support themselves has been undergoing massive changes, and the same is true for most, if not all, organismally-oriented professional societies. Revenue that once came from memberships is being replaced by revenue from electronic access, and with that access, available to most people at universities and museums—at least in developed countries, societies have seen drops in membership. SSAR has suffered less than some societies, but it has suffered nonetheless. When people do not join SSAR because they get *Journal of Herpetology* "for free" through their institution, they are missing much of the point of membership. In addition to the journals, there are meetings and book discounts and other tangible benefits. Then there is the intangible benefit of being part of a society of colleagues who are bound together by shared research and conservation goals and by their interest in a particular group of animals. Membership is a way of sharing in the proud tradition of herpetology as a discipline and of formally associating oneself with this field. It is critical for the continued health of SSAR that we retain and even grow the membership. This is not a purely financial concern. As a society with unpaid officers and editors, our ability to provide the benefits enjoyed by our members is dependent on having a pool of volunteers who will step up and contribute. Student members are vitally important as they are the editors and officers of the future and ensure the continuity of the society and of the products and services that SSAR provides to the herpetological community as a whole.

Another challenge is how we disseminate information about SSAR and how we distribute our publications. SSAR has always been distinguished by its diverse series of publications, featuring *Journal of Herpetology* and *Herpetological Review*, but also including *Herpetological Circulars*, the *Catalogue of American Amphibians and Reptiles* (*CAAR*), and our three book series: *Contributions to Herpetology*, *Facsimiles Reprints in Herpetology*, and *Herpetological Conservation*. Our journals are now distributed both in hard copy and electronically, and CAAR has transitioned to electronic format only. Despite the ubiquity of pdfs, many members still prefer hard copy and for the immediate future we will continue to provide options for journal content delivery. Our other publications remain in high demand and meet the needs of our broad membership, however, book production is changing rapidly and the market for hard copy books has changed in recent years. SSAR will work to continuously evaluate how best to keep costs low, facilitate access, and continue to serve the diverse interests of the herpetological community. Members will have noticed the recent update of the SSAR website (ssarherps.org) and, as a society, we are striving to make the site as useful as possible and to use both it and social media to attract new members and keep current members in contact and up-to-date about publications, services, news, and events.

2015 SSAR Meeting in Lawrence, Kansas

For many years SSAR has annually met jointly with our sister societies, The Herpetologists' League (HL) and the American Society of Ichthyologists and Herpetologists (ASIH). This year, however, we will meet independently of these groups at the University of Kansas in Lawrence and will welcome PARC (Partners in Amphibian and Reptile Conservation), CNAH (Center for North

American Herpetology), the herpetological societies of Kansas, Missouri, and Arkansas, and the International Society for the History and Bibliography of Herpetology, as co-sponsoring societies. While SSAR values its association with HL and ASIH, the Lawrence meeting will provide members with something special. With the 2015 meeting, SSAR returns to its historical origins on a university campus. With fewer participants than a joint meeting and more opportunities to interact, the conference promises to be memorable. For most students, accustomed to hotel and convention center-based meetings, the KU meeting will be a new experience. In addition to traditional activities, like the auction, student social, and president's travelogue, the meeting will feature many special events including a herpetological quiz, live animal display (Kansas species), rare book exhibit, tour of the Henry Fitch Natural History Reserve, and the newly revised and digitized audio-visual shows "Amphibians of the Appalachians" and "Herpetologists Past and Present" not seen for many years. A special reception will honor senior herpetologists, some of whom have not attended our meetings in many years, and will provide students and others with the chance to meet their herpetological heroes. Rounded out by a stellar slate of featured speakers and excellent symposia (see advertisement on pages 150–151 in this issue), the 2015 meetings will be a celebration of herpetology and a showcase for SSAR and its many activities. Thank you for your membership and for your support of SSAR. I look forward to seeing you in Lawrence, Kansas this summer (July 30–August 3, 2015). Be sure to go to SSAR2015.ku.edu to register and see more details about the meeting.

Aaron M. Bauer
President, SSAR

SSAR Student Poster Awards Named for Victor Hutchison

The SSAR Board of Directors recently decided to name its annual awards for the best student posters presented at its meetings in honor of Victor H. Hutchison, the George Lynn Cross Research Professor Emeritus at the University of Oklahoma. Vic is a long-time and active member of the Society, beginning in the 1960s during its primordial stage as The Ohio Herpetological Society. He organized and ran two of our annual meetings: the 1972 session at the Oklahoma Biological Station, located on the north shore of Lake Texoma at the Texas-Oklahoma border, and the 1984 event on the University of Oklahoma's main campus in Norman near Oklahoma City. He was a Director of SSAR in 1986–1988 and served as our President in 1999.

Vic is a native of Georgia and received his master's and doctoral degrees at Duke University under the mentorship of Joseph Bailey and Knut Schmidt-Nielsen. He began his professorial career at the University of Rhode Island and moved to the University of Oklahoma as professor and zoology department chairman in 1970. He had served in the U.S. Army in Korea during 1952–1954 and retired as a full colonel in the active reserve in 1982. His research interests are broad and include environmental physiology; physiological ecology, respiration, and metabolism in amphibians and reptiles; and thermal tolerances in vertebrates. He is perhaps best known to herpetologists for developing the critical thermal maxima concept, research on respiratory gas exchange in amphibians, and for proving experimentally that the heat produced by brooding pythons is due to coordinated spasmodic contractions of the body musculature. He mentored more than 40 graduate students, among them Gustav Engbretson, Terry Graham, Ronald Gratz, James Lazell, Lynette Sievert, Allen Vinegar, and Walter Whitford who received PhDs under his supervision. Vic is a Fellow of AAAS, and he was a Guggenheim Fellow and an NSF Visiting Fellow in Poland. He served as President of ASIH in 1988. He has also been a leader in conservation and science education at the state and national levels. Since 1993 he has served as Editor of the Animal Natural History book series for the University of Oklahoma Press.

It is a distinct honor for SSAR to associate Vic's name with its program to recognize outstanding research conducted by students. Doing so adds greatly to the prestige of these awards.

Herpetological Conservation

A book-length series published by SSAR

Herpetological Conservation is an underused publication outlet devoted to the conservation and management of amphibians and reptiles. Books in this periodic series have been peer-reviewed contributions containing separate chapters and sections. The first two were on Canadian herpetology and the third was on urban herpetology.

I am seeking proposals for the next volume (Number 4). Points that should be addressed: topic is applicable to herp conservation and management, geographic coverage is global in scope or at least broadly regional, and the work makes an important contribution to a topic not well covered by other publications. Send inquiries to Joe Mitchell at dr.joe.mitchell@gmail.com.

NEWSNOTES

Biology of the Reptilia Online Completed

It is with great pleasure that the Gans Collections and Charitable Fund announces that the Biology of the Reptilia is now fully online. This includes all 22 volumes of the set, consisting of approximately 14,000 pages. Visitors to the site CarlGans.org can now browse the full Table of Contents of the series, directly access the Full Content of every volume, and quickly find material through the 26-page A–Z Index of the Entire Series.

Every page is viewable individually in an embedded PDF viewer, where the researcher can quickly jump to the desired page, or browse page by page through an entire volume. Additionally, illustrated plates that were embedded between pages are now available at the end of each volume.

The full series is a major reference work in the areas of Morphology, Physiology, Ecology, Behavior, Neurology, and Development. It is hoped that easy access to this reference guide will inspire and enable further research in these fields.

Posthumous Honor for Ilya Darevsky

IMAGE COURTESY OF IGOR V. DORONIN, RUSSIAN ACADEMY OF SCIENCES, SAINT PETERSBURG

Former SSAR member Ilya Sergeevich Darevsky (1924–2009), academician of the Soviet Academy of Sciences and the discoverer of natural parthenogenesis in reptiles, was recently honored by the Russian Postal Service with a commemorative post card. On December 18, 2014, the 90th anniversary of his birth, a symposium was held to honor him at the Academy of Sciences in Saint Petersburg where he was head of the Division of Herpetology and Ornithology. Darevsky became a member of the society in the mid-1960s. His first published paper in English appeared in the society's Journal in 1966, which introduced his important research to a wide audience in Western countries. For more details on his life, see his obituary in *Herpetological Review*, vol. 40, pages 401–403, 2009.

2014 Sabin Conservation Prizes

Sabin Conservation Prizes for 2014 were awarded at a special luncheon held in New York City on 20 January 2015. Emcee Russ Mittermeier noted that species-based conservation support is generally decreasing, making the awards provided by the Sabin Family Foundation especially important. Each awardee received a US $20,000 honorarium.

The 2014 Sabin Turtle Conservation Prize was awarded to **Margaretha Hofmeyr**, Emeritus Professor in the Biodiversity and Conservation Biology Department at the University of the Western Cape in South Africa. Her research initially focused on large mammals but she switched to chelonians when she resumed her research career after raising three children. In 1996 she initiated and developed a research program on Chelonian Biodiversity and Conservation for South Africa, and that has been her focus ever since. Living in the world's center of tortoise species richness, she has worked and published on many species of *Psammobates, Homopus, Kinixys, Chersina, Stigmochelys* and the turtle *Pelomedusa*. Her work on the Geometric Tortoise (*Psammobates geometricus*) has been critical to the continuing survival of this species. After the 2012 fire that destroyed at

PHOTO BY OF TURTLE CONSERVANCY/M. MAURER

Margaretha Hofmeyr, shown here receiving the 2014 Sabin Turtle Conservation Prize from Andrew Sabin (left) and Eric Goode (center).

least half of the population at the Elandsberg Reserve, she was instrumental in leading the recovery program for that population, formerly the largest known of Geometric Tortoises. She pioneered semi-captive management and breeding and has developed a workable head-start method for this species, which has never been bred in captivity. She collaborates widely with other tortoise biologists and works closely with several governmental conservation agencies. Recently, she led South Africa's submission to the IUCN Tortoise and Freshwater Turtle Specialist Group's Red-listing meeting in Togo for sub-Saharan chelonians. This work has resulted in the uplifting of several South African species, including the Geometric Tortoise. Her combination of broad scale strategic planning and closely focused fieldwork has put her in the front ranks of turtle conservationists. Her current research focuses on the diversity, distribution and niche requirements of southern African tortoises, and the conservation management of Geometric Tortoises.

PHOTO COURTESY OF TURTLE CONSERVANCY/M. MAURER

Carlos Vásquz Almazán is shown here accepting the 2014 Sabin Amphibian Conservation Prize from Andrew Sabin (left) and Robin Moore (center).

The 2014 Sabin Amphibian Conservation Prize was awarded to **Carlos Vásquez Almazán**, a rapidly emerging leader in the conservation of Central America's amphibians. Carlos is effectively bridging the gaps among science, conservation action, and community engagement to identify and protect some of the most critical habitats in Guatemala.

Carlos was instrumental in one of the landmark success stories of recent years: the creation of the Sierra Caral Amphibian Reserve. The reserve, which protects the single most biodiverse forest remnant in Caribbean Guatemala and numerous amphibians found nowhere else, was recently expanded by the Guatemala National Congress to encompass 47,000 acres of lush forest.

Carlos continues to build on the success of the Sierra Caral by working with local and international partners towards the protection of the rich forests of the Cuchumatanes Mountains of northwest Guatemala, home to several endemic and Threatened salamanders and frogs.

SSAR congratulates Margaretha Hofmeyr and Carlos Vásquez Almazán for this recognition, and also acknowledges the critical support from Andrew Sabin for his important role in encouraging these conservation initiatives.

—Submitted by Ross Kiester

The Kenya Reptile Atlas

With initial funding from the Rufford Foundation and supported by the National Museum of Kenya, a team of five herpetologists—Stephen Spawls, Patrick Malonza, Beryl Bwong, Victor Wasonga, and Vincent Muchai—are producing a free online atlas of all of Kenya's reptiles, available at www.kenyareptileatlas.com. For each species there is a map, showing the distribution of that species within Kenya by quarter-degree squares, color illustrations, often several showing different forms, and a description. At present, accounts are available for all of Kenya's vipers, elapids, burrowing snakes (Atractaspidinae and Aparallactinae), chameleons, agamas, and medically important rear-fanged snakes, plus fully updated checklists for all of Kenya's reptiles. To obtain any account go to the website and click on downloads. Eventually, accounts for all Kenyan reptile species will be available, to be followed by regular updates. We encourage herpetologists to please spread the word, download the material, and use it as you see fit. We are particularly keen that schools and other educational institutions make use of the data. Any picture that's not marked as copyright belongs to Steve Spawls and anyone is welcome to use those pictures. Anyone wanting want high-resolution scans of any pictures by Steve, contact him at stevespawls@hotmail.com. We encourage participation and contribution; if you have photographs of any Kenya reptiles, please send them to Kenyareptileatlas@gmail.com. Anyone in Kenya finding specimens is urged to deposit them at the Herpetology Section at the National Museum in Nairobi.

MEETINGS

Meeting announcement information should be sent directly to the Editor (herpreview@gmail.com) well in advance of the event. We also welcome brief reports of meetings; please consult the Editor for details.

2–5 April 2015—62nd Annual Meeting of the Southwestern Association of Naturalists, San Diego, California, USA. Information: http://www.biosurvey.ou.edu/swan/annualm.html

18–19 April 2015—Terrapin, Tortoise & Freshwater Turtle Meeting, Dalaman, Mugla, Turkey. Information: Chelonian1@aol.com (Chuck Schaffer).

19–24 April 2015—35th Annual Symposium on Sea Turtle Biology and Conservation, Dalaman, Muğla, Turkey. International Sea Turtle Society. Information: http://iconferences.seaturtle.org/

27–30 May 2015—38th Annual International Herpetological Symposium, San Antonio, Texas, USA. Information: www.internationalherpetologicalsymposium.com

15–19 July 2015—American Society of Ichthyologists and Herpetologists and The Herpetologists' League annual meeting, Reno, Nevada, USA. Information: www.asih.org

27–29 July 2015—World Conference on Monitor Lizards, Bangkok, Thailand. Information: monitor.conference.2015@gmail.com (and see announcement below).

30 July–3 August 2015—58th Annual Meeting of the Society for the Study of Amphibians and Reptiles (with Partners in Amphibian and Reptile Conservation, Kansas Herpetological Society, and International Society for the History and Bibliography of Herpetology), Lawrence, Kansas, USA. Information: www.SSAR2015.ku.edu

18–20 August 2015—Northeast Partners in Amphibian and Reptile Conservation (NEPARC) annual meeting, Greenwich, Rhode Island, USA. Information: http://northeastparc.org/next-meeting-info/

Brief Review of the XIII National Mexican Herpetological Meeting

From 4–7 November 2014, the XIII National Meeting of Herpetology was hosted by the Universidad Autónoma de Aguascalientes, organized by Sociedad Herpetológica Mexicana A. C. (SHM). The overall event was coordinated by the executive board of 2012–2014: MSc. Gustavo Ernesto Quintero-Diaz (President), Dr. Víctor H. Luja-Molina (Vice President), Dr. Jorge E. Morales-Mávil (Secretary General), MSc. Jazmín Cobos-Silva (Treasurer), MSc. Roberto Luna-Reyes (Southern Representative), MSc. Henry Fahd Carmona-Torres (Central Representative), and Biol. Javier Banda-Leal (Northern Representative). Herpetologists from several countries, including Argentina, Brazil, Colombia, Cuba, Honduras, United States of America, and Mexico, were in attendance to discuss topics on Mexican amphibians and reptiles.

Attendees at the XIII National Mexican Herpetological Meeting, Aguascalientes, Mexico.

During the meeting five distinguished speakers made presentations invited by the SHM. In addition two symposia and five workshops/courses were offered. In all there were 111 oral and 72 poster presentations, of which 41 were formal degree presentations.

Five new or recently published books were presented. The first was *Theoretical and Methodological Guide on the Information and Handling of Herpetofauna*, by MSc. Gustavo Jiménez-Velázquez, Biol. Jaén Alberto Sandoval-Quintero, and Dr. Nuri Trigo-Boix. Dra. Ireri Suazo-Ortuño gave an overview of the book.

The second was *Amphibians and Reptiles of Hidalgo, Mexico: Diversity, Biogeography and Conservation*, by Dr. Aurelio Ramírez-Bautista, MSc. Uriel Hernández-Salinas, MSc. Raciel Cruz-Elizalde, Biol. Christian Berriozabal-Islands, Biol. Daniel Lara-Tufino, Dr. Irene Goyenechea-Mayer, and MSc. Jesus M. Castle-Ceron. The book was presented by MSc. Guadalupe Gutiérrez-Mayén, who spoke eloquently about the history of the book and received positive comments for the authors.

The third and fourth books were *The Turtles of Mexico. Land and Freshwater Forms*, by John M. Legler and Richard C. Vogt; and *The Turtles of Amazonia*, by Richard C. Vogt. The fifth book, *Guide of Amphibians and Reptiles of Charco Azul, Xichú, Guanajuato*, by Dr. Adrián Leyte-Manríquez and Biol. Matías Domínguez-Laso, was presented by Dr. Jesús Sigala-Rodríguez.

Among the speakers was Dr. Rulon W. Clark, Professor in the Department of Biology, San Diego State University (USA). Dr. Clark focused on predators and anti-predator behavior of rattlesnakes. We also received a presentation by Dr. Sean M. Rovito on the evolution of lungless salamanders. Dr. Rovito is a research professor at the National Laboratory of Genomics for Biodiversity (CINVESTAV) in Mexico and presented a discussion on "New revelations about an adaptive radiation."

Dr. Richard C. Vogt, researcher at the National Institute for Research in the Amazon (Brazil), presented "Acoustic communication in aquatic turtles." Two other presentations were offered, the first by the leading researcher in Mexico on amphibians, Dra. Gabriela Parra-Olea, from the Institute de Biologia (UNAM), who addressed the issue of "Emerging infectious diseases and the decline of amphibians." In the second, Biol. Roberto Arreola-Alemón of CONABIO spoke about "Citizen science, social networks and their contribution to the understanding of the amphibians and reptiles of Mexico."

Worth special mention were two symposia conducted within the XIII Reunion Nacional de Herpetologia. The first symposium was organized by Dr. Oscar Flores-Villela from the Facultad de Ciencias (UNAM). This consisted of an eloquent tribute to Dr. Hobart Muir Smith, prominent scientist from the United States who spent much of his lifetime on the study of the amphibians and reptiles of Mexico. The event was conducted by his son, Bruce Smith (accompanied by wife Dorothy and daughter Rebecca). In addition, we were honored with the presence of Mr. Miguel Cerón-Herrera, now 95 years of age, whose experience as expressed by himself and his daughter, transported the attendees to the mountains of Veracruz, the site where, as children, he and his brother had first been contacted by Dr. Hobart Smith. The Cerón brothers were the ones who guided Dr. Smith and other visiting researchers to many collecting sites in the area.

The second symposium was coordinated by Dr. Jesús Sigala-Rodríguez (Universidad Autónoma de Aguascalientes) and presented topics on "Poisonous Snakes." In the symposium, Dr. Sigala-Rodriguez presented the "Specialist Group" and gave a presentation on viperids and the International Union for the Conservation of Nature. Additional presentations included: Dr. Ana Gatica-Colima (Universidad Autónoma de Ciudad Juárez), "The state of conservation of rattlesnakes in the desert area of northwest Mexico;" Alan Kardon (San Antonio Zoo), "Maintenance and captive reproduction of new world pitvipers at the San Antonio Zoo;" Dr. David Lazcano (Universidad Autónoma de Nuevo Leon, Facultad de Ciencias Biológicas), "Variation in body weight in three mountain species of rattlesnakes, *Crotalus aquilus* (Klauber, 1972), *Crotalus lepidus* (Kennicott, 1861) and *Crotalus willardi* (Meek, 1905), under captive conditions."

Biol Raúl Hernández-Arciga (Herpetario de San Luis de la Paz, Guanajuato) presented a "National snake panorama review;" Dr. Alejandro Carbajal-Suacedo (Herpetario Kuiana) presented "Protocol for safe handling of snakes"; Biol. Guillermo Gil-Alarcón (Departamento de Prevención de Riesgos de la Dirección General de Divulgación de la Ciencia [DGDC], Universum, Museo de las Ciencias, de la UNAM) presented "Network support for snake accidents;" and the last presentation was given by MSc. Gustavo Jiménez-Velázquez (UNAM and Vida Silvestre Cóatl A.C) titled "Geographic and ecological distribution of mountain rattlesnakes via an ecological niche modeling and its application in their conservation."

Additionally, more than 60 photographs of amphibians of Mexico, provided by MSc. Roberto Luna-Reyes, were exhibited to highlight conservation of amphibians in Chiapas.

As a final event, a general plenary of the SHM took place and the outgoing executive board presented its report. In the same assembly, a new executive board was elected for the period

(2014–2016), and consists of Dr. Víctor H. Luja-Molina (President), MSc. Guadalupe Gutiérrez-Mayén (Vice President), Dr. Ana Gatica-Colima (Secretary General), MSc. Jazmín Cobos-Silva (Treasurer), MSc. Roberto Luna-Reyes (Southern Representative), Biol. Guillermo Gil-Alarcón (Central Representative), and MSc. Anny Peralta-Garcia (Northern Representative).

Students who attended and presented their projects could enroll in five different workshops/courses: 1) "Principles of GIS (Geographic Information Systems) maps with quality for publication" (Biol. José Carlos Arenas-Monroy, Laboratorio de Herpetologia, Facultad de Ciencias, UNAM); 2) "Management of poisonous reptiles" (MSc Eric Abdel Rivas-Mercado, Universidad Autónoma de Aguascalientes; 3) "First aid, update on the study of poisons and treatment in snake accidents" (Biol. Guillermo Gil-Alarcón, Dr. Alejandro Carbajal-Saucedo, and MSc. Fahd Henry Carmona-Torres (UNAM); 4) "Methods for estimating biodiversity" (MSc. Victor Hugo González-Sánchez, Universidad Autónoma de Aguascalientes); 5) "Techniques for rock climbing in herpetology" (Biol. Juan Daniel Rendon-Trinidad, Universidad Autónoma de Aguascalientes).

Anyone interested in Mexican herpetology is welcome to become a member of the society. We also encourage researchers interested in working in Mexican herpetology to contact any members of the board for information. For those interested in obtaining copies of the latest program of activities please consult our web page (http://www.sociedadherpetologicamexicana.org/). The new executive board plans to update the web page, as well as publish our new electronic journal (*Revista Mexicana de Herpetologia*) for all members and welcomes contributions to the journal. Our next meeting for November 2016 will be hosted by the Universidad Autónoma de Nayarit; this will be the first time the meeting will take place there. Nayarit, like many states of Mexico, is a beautiful place for any type of academic activity.

We thank Dr. Robert L. Bezy (Natural History Museum of Los Angeles County) and Dr. David Lazcano (Universidad Autónoma de Nuevo León) for their suggestions and helping out with the English version of this manuscript, and for documenting this important event for all of us that enjoy working with Mexican herpetology.

HERPETOLOGICAL NOMENCLATURE

The years 2013–2014 have been especially controversial ones insofar as herpetological nomenclature is concerned. It began with an article in this journal by Kaiser et al. (2013) recommending a standard of best practices for systematic herpetology. The article in particular reviewed the practices of R. T. Hoser and his notorious *Journal of Australasian Herpetology*. In that "journal" he has created hundreds of taxonomic names proposed in ways that most herpetologists think do not meet the conditions for publication required by the International Code of Zoological Nomenclature (International Commission of Zoological Nomenclature 1999). In what is clearly a ploy to legitimatize his journal, Hoser has applied to the Commission in Case 3601 (see below) to endorse his claims that his "journal" meets the requirements of the Code thereby making his multitude of new names available.

Kaiser et al. (2014) countered Hoser's contentions and there is widespread support in the herpetological community for placement of all issues of the *Journal of Australasian Herpetology* on the Index of Rejected and Invalid Works in Zoological Nomenclature. This action is certainly within the purview of the Commission under Arts. 78 and 81 relating to the Plenary Power, which may be invoked to suppress a particular name or works that would "disturb stability or universality or cause confusion."

The problems raised by the Hoser case clearly test the long held notion that the Commission not make judgments on the taxonomic quality of an author's work by applying the Code in as neutral manner as possible. Nevertheless, in ruling on individual cases presented to the Commission, the attempt at neutrality is not uniformly successful. In almost all cases, there are differences of opinion among the Commissioners, hence the requirement that approval of most applications be a simple majority, but where the Plenary Power is involved a two-thirds majority is required for approval. Because of these concerns, Commissioners Harvey and Yanega (2013) prepared a brief, very thoughtful, document requesting advice from the taxonomic community as a whole on possibly changing the guidelines for Commission actions to deal with such extreme cases as Hoser's. They asked that responses address the issues they raise not the specific case that has led to the controversy. The results of their survey have not yet been published and there is still time to comment anonymously on their questions via the Commission website.

While all this activity was going on, major changes took place in the location and operations of the Commission. A major financial crisis led to the dissolution of the International Trust for Zoological Nomenclature that had long been the financial entity supporting Commission activity. In another move, the University of Singapore agreed to provide space and staff for the coordinating activities of the Commission, for three years. A small staff, including the editor of the *Bulletin of Zoological Nomenclature* (BZN), will remain at the Natural History Museum in London. Visit the ICZN website (http://iczn.org/) for more details. The University of Singapore's rescue is temporary and it remains to be seen if the Zoological community will rise to the occasion and develop a funding plan that insures the continuance of the vital functions of the Commission.

Recent Rulings on Herpetological Names
(BZN = *Bulletin of Zoological Nomenclature*)

Opinion 2328 (Case 3571). *Crotalinus catenatus* Rafinesque, 1818 (currently *Sistrurus catenatus*) and *Crotalinus tergeminus* Say in James, 1822 (currently *Sisturus tergeminus*; Reptilia, Serpentes): usage conserved by designation of neotypes for both species. BZN 70(4):282–283.

Opinion 2331 (Case 2331) *Cetiosaurus* Owen, 1841 (Dinosauria, Sauropoda): usage conserved by designation of *Cetiosaurus oxoniensis* Philipps, 1871 as the type species. BZN 71(1):48–50.

Opinion 2350 (Case 3566) *Tropidolaemus* Wagler, 1830 and *Cophias wagleri* F. Boie, 1827 (currently *Tropidolaemus wagleri*) (Reptilia, Squamata, VIPERIDAE): usage conserved. BZN 71(4):271–273.

Pending Cases of Herpetological Interest

Case 3625. *Kinosternon chimalhuaca* Berry, Seidel, & Iverson in Rogner, 1996 (Reptilia, Testudines): proposed confirmation of the publication date. BZN 70(3):190–102.

Case 3628. *Terrapene putnami* Hay, 1906 (Testudines, EMYDIDAE): replacement of the holotype by designation of a neotype. BZN 70(3):193–198.

Case 3601. *Spracklandus* Hoser, 2009 (Reptilia, Serpentes, Elapidae): Request for the confirmation of the availability of the generic name and for the nomenclatural validation of the journal in which it was published. BZN 70(4):234–237.

Case 2641. *Ascalabotes sthenodactylus* Lichtenstein, 1823 (currently *Stenodactylus sthenodactylus*; Reptilia, Gekkota, GEKKONIDAE): proposed conservation of current usage of the specific name by designation of a neotype. BZN 71(1):17–21.

Case 2629. *Vipera latastei* Boscá, 1878 (Reptilia, Serpentes, VIPERIDAE): request for conservation of the original spelling. BZN 71(1):22–25.

Case 3666. Dicroglossidae Dubois, 1987 (Amphibia, Anura): proposed conservation. BZN 71(4):244–249.

CURRENT RESEARCH

The purpose of Current Research is to present brief summaries and citations for selected papers from journals other than those published by the American Society of Ichthyologists and Herpetologists, The Herpetologists' League, and the Society for the Study of Amphibians and Reptiles. Limited space prohibits comprehensive coverage of the literature, but an effort will be made to cover a variety of taxa and topics. To ensure that the coverage is as broad and current as possible, authors are invited to send reprints to the Current Research section editors, Ben Lowe or Chava Weitzman; e-mail addresses may be found on the inside front cover.

Acoustic Mimicry of Vipers in a Natricine Snake

It is generally accepted that snakes hiss to intimidate potential predators and dissuade large herbivores from trampling them. A special case of the former that has been hypothesized is that hissing in harmless snakes may sometimes serve to increase resemblance to a venomous species, principally vipers. To test this hypothesis in a suspected case of Batesian mimicry, the authors of this study made audio recordings of three snake species: Asp Viper (*Vipera aspis*, the model), Viperine Snake (*Natrix maura*, the suspected mimic), and Grass Snake (*Natrix natrix*, not considered a viper mimic and included as a control). Animals were collected along the Lez River in southwestern France, measured and recorded hissing in the laboratory, and released. Hissing in snakes consists of four elements: inhalation, exhalation (generally the loudest element), and brief pauses after each. Focusing on exhalation, various spectral components of this element were teased out and included in a principal component analysis (PCA), and each spectral component was evaluated independently across the species in an ANOVA. Furthermore, in- and exhalation duration variation was investigated with respect to species and size using general linear models. These investigations revealed size was not correlated with exhalation duration, and the species did not differ in exhalation duration. To the contrary, inhalation length of Asp Vipers was significantly longer than for *Natrix*, and while all Asp Vipers and most Viperine Snakes performed the inhale element, only a quarter of Grass Snakes did so. Plotting the first two axes from the PCA showed the Asp Viper and Grass Snake form non-overlapping clusters, while the Viperine Snake occupies a broader space that greatly overlaps those of the other two species. ANOVAs performed on the spectral component data showed the species differed significantly, and post-hoc tests revealed the Grass Snake hiss differed significantly from that of the Asp Viper and Viperine Snake, but that the latter two were indistinguishable. The authors argue this hiss similarity is best explained as selection on Viperine Snakes to resemble Asp Vipers, a similarity which had plenty of time to evolve as phylogeographic evidence suggests the two species have been sympatric for 22 million years.

Factors Associated with Non-Native Reptile Establishment Success Identified

Introduction and establishment of non-native species was a common phenomenon in the twentieth century, and promises to be so in the twenty-first as well. Numerous studies have investigated invasive species with the goal of identifying

characteristics correlated with successful establishment, however, most of these studies focused on regional fauna. With the hopes of bringing a global perspective and rigorous methods to this question, the authors of this paper made use of a previously-published dataset of 1307 reptile introductions (involving 398 species), 708 of which have progressed to establishment. Following supplementation by the authors, this dataset included 32 variables divided between three general categories: 1) ecology/life history, 2) geographic specifics of introduction, and 3) non-geographic specifics of introduction. (The latter category included time since introduction, number of prior introductions, and intentional vs. accidental.) This dataset was analyzed using generalized linear mixed modeling methods, which identify statistically significant correlates from a set of variables. Each of the three categories were analyzed independently to identify important variables within each category, and variables found to meet a relaxed threshold of support in these analyses were subsequently analyzed in a "global" analysis allowing comparisons between categories. The authors found variables that correlate with successful introduction in each of the three general categories: 1) parthenogenesis, an herbivorous diet, a large native range, 2) a small latitudinal differential between native and introduced ranges, the presence of congeners in the area of introduction, 3) longer time since first introduction, and number of introductions. The global analysis found category 2 (geographic specifics of introduction) explained the highest proportion of establishment success variation, followed by the non-geographic introduction specifics, followed by the ecology/life history traits. Two additional ecology/life history characteristics, high fecundity and small size, were identified as important in the global analysis, and one of the category 2 traits found to be important in the category specific analysis (presence of congeners) became non-significant. The authors point out this is the first study to quantify the importance of parthenogenesis in invasive species establishment, and stress the importance of taking life history and ecology into account when considering the risk of non-native reptile introductions.

Hot, Dry Costa Rican Peninsula a Climatic Refuge from *Bd*

The persistence of *Bd*-vulnerable frog species in some habitats despite extirpation elsewhere has led researchers to propose the "climatic refuge" hypothesis, in which climatic conditions unfavorable to the growth of *Bd* protect these populations from the fungal infection. One climatic refuge from *Bd* has been demonstrated in Australia's Wet Tropics, and as another region that has experienced devastating amphibian declines, Costa Rica also represents a potential place to find climatic refuges from *Bd*. The authors of this paper surveyed two frog communities for *Bd*: one on the Costa Rica's Santa Elena Peninsula, the country's driest region and most likely a climatic refuge from *Bd*, and the Sector Santa Rosa del Área de Conservación Guanacaste (Santa Rosa), a site 16 km away from the first but considerably cooler and wetter, serving as a control. Areas were surveyed two consecutive years at the beginning of the wet season. This entailed swabbing all frogs encountered as well as checking them for visible pathology related to *Bd*. Of special interest was the species *Craugastor ranoides*, which was widespread across Costa Rica but has recently become extirpated from all but the Santa Elena Peninsula (and is considered highly susceptible to *Bd*). Swabs were assayed for *Bd* presence and load through real-time PCR methods. Additionally, employing temperature and precipitation data layers, GIS methods were performed to determine if the climatic envelope for extant *C. ranoides* populations differed from that of the recently extirpated populations. Out of 310 Santa Elena Peninsula samples (114 of which were *C. ranoides*), only one (a *C. ranoides*) tested positive for *Bd*. Prevalence was higher at Santa Rosa (9 of 100), with the Tungara Frog (Leiuperidae: *Engystomops pustulosus*) being the most frequently infected (6 of 19). At both locations, the highest zoospore counts observed were an order of magnitude lower than the count widely recognized to be fatal and/or representative of a mass outbreak (10,000 zoospores), and no *Bd*-associated pathology was seen. The climatic envelope of the extant *C. ranoides* populations was indeed outside the envelope encompassing the extirpated populations, with the Santa Elena Peninsula localities being drier than all and hotter than most extirpated populations. The low prevalence of *Bd* in the Santa Elena Peninsula, coupled with the persistence of a species considered vulnerable to *Bd* supports the hypothesis that this hot, dry area is serving as a climatic refuge for anurans.

Zumbado-Ulate, H., F. Bolaños, G. Gutiérrez-Espeleta, and R. Puschendorf. 2014. Extremely low prevalence of *Batrachochytrium dendrobatidis* in frog populations from Neotropical Dry Forest of Costa Rica supports the existence of a climatic refuge from disease. EcoHealth (*in press*) doi: 10.1007/s10393-014-0967-2.

Rapid Thermal Acclimation in Australian Cane Toads

The ecology of Cane Toads (*Rhinella marina*) in Australia has been studied intensely, due to the insights into invasion ecology afforded. Observations of the toads occupying Australian regions cooler than those occupied in most of their native range led the authors of this paper to examine thermal tolerance and acclimation in toads occurring at two cool, high-elevation sites within Border Ranges and Nightcap National Parks, New South Wales. Toads were collected from these sites as well as two nearby warmer, low elevation sites (control) and tested immediately to determine at what low temperature they were unable to right themselves (CTmin). Toads from two high and two low locations were also brought into the laboratory, and animals from each population were split between high- and low-temperature acclimation treatments (24 and 12°C, respectively). After four weeks,

the toads in each treatment were further divided between "test temperature" treatments of 12 and 24°C and left for 12 hours. Subsequently, toads were tested for speed and endurance on a "race track," allowed to rest for an hour, then evaluated for their CTmin. Finally, an ANOVA analysis was performed to identify correlates of CTmin, hopping speed, and stamina among the treatments. High elevation toads evaluated in the field had significantly lower CTmins that low elevation toads. Remarkably, for a given test temperature, toads did not differ in CTmin, regardless of collection elevation or acclimation temperature. The test temperature did affect CTmin: toads held for 12 hours at 12°C had significantly lower CTmins than toads held at 24°C. Conversely, while acclimation temperature had little effect on speed and endurance of toads in the 12°C test temperature treatment, toads acclimated at 24°C performed better in the 24°C test temperature treatment than did toads acclimated at 12°C, and low elevation toads acclimated at the warm temperature performed better in the warm test temperature treatment than did similar toads acclimated at 12°C. Also, high-elevation toads showed similar endurance in both the low- and high-test temperatures. The authors argue the CTmin findings imply that toads are meeting thermal challenges through acclimation rather than adaptation, as only the temperature experienced over the last 12 hours affects CTmin. They also stress that estimates of areas vulnerable to Cane Toad invasion based on data from their native range may be vastly underestimated.

McCann, S., M. J. Greenlees, D. Newell, and R. Shine. 2014. Rapid acclimation to cold allows the cane toad to invade montane areas within its Australian range. Functional Ecology 28: 1166-1174.

Two New Philippine Monitors Described

Our collective understanding of herpetofaunal diversity and distribution in the Philippines has increased considerably over the last 15 years, due largely to molecular phylogenetics and unprecedented survey efforts. Recent studies of the *Varanus salvator* species complex (water monitors) have led to descriptions of new Philippine species and identification of other populations that may deserve species status. The authors of this study describe two of those populations as new species. These species are represented as two reciprocally monophyletic and geographically cohesive lineages in a phylogeny generated by an analysis of a concatenated mitochondrial and nuclear gene dataset. Despite morphologically matching a widespread Philippine species, *V. marmoratus*, this phylogeny suggests these new species may be each more closely related to other, morphologically diagnosable members of the complex. One new species, *V. bangonorum*, is restricted to the islands of Mindoro and Semirara, which are southwest of Luzon. The other new species, *V. dalubhasa*, occurs on the Bicol Peninsula of Luzon and several adjacent islands. Despite presumably being in geographic contact with *V. marmoratus*, the specific status of *V. dalubhasa* is not entirely surprising, as the Bicol Peninsula is increasingly being recognized as being biogeographically distinct from the rest of Luzon. These new species are truly cryptic—no morphological characters separate them from *V. marmoratus*. However, each new species exhibits a unique gular pigment pattern not seen in other closely related *Varanus* in the Philippines. The authors argue that these species delimitations are strongly supported by multiple lines of evidence (phenotypic, genetic). Further, they discuss the importance of identifying cryptic species in the Philippines, where wildlife is facing heavy pressure from habitat destruction and illegal harvesting.

Welton, L. J., S. L. Travers, C. D. Siler, and R. M. Brown. 2014. Integrative taxonomy and phylogeny-based species delimitation of Philippine water monitor lizards (*Varanus salvator* complex) with descriptions of two new cryptic species. Zootaxa 3881:201–227.

Molecular Investigation of a Continentally Distributed Amphibian Species

Molecular phylogenetic studies in the 21st century have relegated many species once considered continentally distributed to complexes of cryptic species with distinct geographic distributions, leaving few remaining continentally distributed amphibian species in the Neotropics. The Lesser Treefrog, *Dendropsophus minutus* (Hylidae), is one such species. It is distributed across much of northern and central South America in both open and forested habitats, and previous regional studies have hinted at species-level differences in this taxon. The authors of this study used phylogeographic methods to evaluate the genetic diversity and historical biogeography across the distribution of *D. minutus*. In what they call, "a roadmap for future integrative studies," they collected mitochondrial DNA sequence data for 407 *D. minutus* and related species (members of the *D. minutus* species group) to generate a time-calibrated estimate of their phylogenetic relationships. These analyses confirmed the monophyly of *D. minutus*, within which 25 mitochondrial lineages were recovered. Using the branching pattern of the mitochondrial gene tree, they inferred the likely biogeographic history of the *D. minutus* species group, hypothesizing, an origination in the Amazon Basin in the Early to Middle Miocene. This was followed by a Late Miocene dispersal to eastern Brazil, where the lineage leading to *D. minutus* began to diversify in the Atlantic Forest. Subsequently, *D. minutus* expanded its range westward across Brazil to the Andes. The authors stress that subsequent studies are required to determine if any of the mitochondrial lineages within *D. minutus* should be described as distinct species, as the degree of coexistence of divergent mitochondrial clades could alternatively be due to geographic overlapping of previously isolated populations of conspecifics. They conclude by highlighting the need to identify cryptic species in an age of amphibian extinctions, and pointing out that cryptic species within widespread taxa can only be identified through collaborative, multi-national projects.

Gehara, M., A. J. Crawford, J. Köhler, and colleagues. 2014. High levels of diversity uncovered in a widespread nominal taxon: continental phylogeography of the Neotropical tree frog *Dendropsophus minutus*. PLoS ONE 9:e103958.

Gene Expression Following *Bd* Infection Varies at Both Species and Individual Level

The fungal pathogen *Bd* has recently been shown to suppress the immune system of highly susceptible frog species through lymphocyte activity inhibition. In an effort to determine how susceptible and resistant species compare in this regard, the authors of this paper exposed frogs of four Central American species (five to twelve individuals each) to *Bd*, and analyzed gene expression between experimental and control individuals. One included species, *Atelopus zeteki* (Bufonidae), is highly susceptible and extinct in the wild, while the three remaining species, *A. glyphus*, *Agalychnis callidryas* (Hylidae), and *Craugastor fitzingeri* (Craugastoridae) seem to be less susceptible to *Bd*. On a weekly basis post-exposure, each frog was swabbed, and *Bd* presence and load was determined via quantitative PCR. Frogs were euthanized after several weeks or at first sign of advanced *Bd* infection (loss of righting reflex). Gene expression profile at time of euthanasia was characterized through next generation sequencing of the transcriptome, which allows assessment of both RNA transcript presence and relative abundance in specific tissues. The authors sampled the transcriptomes of both skin (primary site of *Bd* infection) and spleen (site of lymphocyte accumulation and proliferation in frogs). All transcripts present in all four species were identified, their concentration was quantified for each sample, and significant differences in expression relative to controls and heterospecifics were identified. Huge differences in *Bd* infection load (five orders of magnitude) were seen among the four species, with *A. zeteki* exhibiting the highest and *A. callidryas* exhibiting the lowest level of infection. In the skin, an astounding number of gene upregulations were shared by infected *C. fitzingeri* and *Atelopus* spp., many of which were identified as serving an immune function. In contrast, scant genes were found to be upregulated in the skin of infected *A. callidryas*, indicating reduced inflammation. Conversely, a suite of genes important for lymphocyte activity and proliferation was found to be significantly upregulated in infected *A. callidryas*, more so than in the other species. Importantly, expression levels of one suite of skin genes and three suites of spleen genes were correlated with *Bd* load. The authors posit that lymphocyte activity and the ability to avoid the immunosuppressive effects of *Bd* are likely the key to *Bd* resistance. Further, the identification of genes whose activity is correlated with *Bd* infection demonstrates a connection between gene expression and *Bd* susceptibility at the individual level and provides a roadmap for future genomic studies of this pathogen.

LETTERS TO THE EDITOR

Giving Talks at Meetings

Going to scientific meetings is important, even if costly in time, energy, and money. The value in meetings is in hearing about new work in the field, meeting old and making new friends, discussing, gossiping and exchanging information and ideas. If current meetings cost so much and the speakers don't know how to present their papers (so you are in fact not learning anything from them), then attendees are not getting a cost effective deal.

I have attended many meetings of many societies, given papers at most, and been a judge of papers at some. Most (but not all) of the professors that present papers know how to talk to an audience. But most of the other talks, maybe 80% of them, and especially government employees, consultants, and graduate students, are poorly given. They present too much data, don't know how to speak loud, enunciate their words, project their voice, or use the mike! Thus 80% of my time listening to papers is a waste of time, money, and energy!

At a recent meeting, a person presented a paper on an animal that I encounter frequently and wanted to know more about. The person gave the paper with interesting slides. Later I happened to be in a lunch line with the speaker. I introduced myself and said that from the slides (though they had no color code), I gathered that the talk was interesting, but that I had heard hardly any of it. I suggested that the person might try to speak louder, be less monotonic, use the microphone, and talk to the audience, not the slides. The person turned around, probably somewhat discombobulated at my remarks…but teachers always try!

About a year later at another meeting, the same person gave another paper on the same fun animal. I wanted to learn more, so I sat in the front row! By the way, at 85 my hearing is still pretty good! The person went up to the podium, put the mike in front, then stepped BACK a few steps so the mouth was about a meter from the mike. The person then gave the talk in a low, almost inaudible monotone. The slides were good, but still no key to the colors used. I was frustrated, but teachers charge on! So in hopes of improving a better transfer of knowledge, getting something for my money in future meetings, and hopefully helping some people get the jobs or grad school they want, I present here a series of suggestions on how to be a better speaker.

1. If you have something to say, SAY IT LOUD, SO EVERYBODY CAN HEAR IT! This is not a conversation or committee meeting. It is a TALK, a PRESENTATION to an AUDIENCE of dozens or hundreds of people, so speak to them, not to the screen, not your notes, not just your friends in front row, TO ALL OF THEM. And PRACTICE, PRACTICE, PRACTICE!

BAYARD H. BRATTSTROM
Horned Lizard Ranch, P.O. Box 166, Wikieup, Arizona 85360, USA
e-mail: bayard@hughes.net

2. Don't tell the audience what you are going to talk about, JUST START!
3. Do not spend 2/3 of your talk telling us about all the details of your methods and all the statistical tests you used because:
   a. It leaves no time for results.
   b. Nobody cares! There may be one or two people in the audience who do, but they will ask you about it later.
   c. It suggests that your data are so weak that you had to search and search to find a statistical test to finally show that your results are significant.
4. Don't tell unrelated stories about people, or "in" jokes. This is a professional, scientific meeting and the people in the audience have spent a lot of time and money to come to hear what you have to say, so be professional!
5. Try this:
   1 minute: Introduction.
   1 minute: Materials & Methods.
   10 minutes: Results.
   1 minute: Conclusions.
   = 13 minutes, leaving 2 minutes for questions.
6. Scan the audience as you talk. Talk to the whole audience. Tailor your message to this audience. Is anyone in the audience holding their hand up to their ear? If so, speak LOUDER!
7. Pay attention to your moderator and respond quickly when the moderator gives you end-of-the-talk timing clues. PRACTICE YOUR TIMING!
8. If there is a screen monitor, glance at it, not the screen. You should have practiced enough so that you know which slide is going to appear next; a quick glance to see if it is the right one is enough, then talk to your audience.
9. Don't be too nervous, or too relaxed. Do some deep breathing in your seat before you get up to talk.

Pictures, Slides, and Graphs

1. Do not show big complicated tables with lots of statistics. Nobody can read them! Don't use your manuscript tables, instead…
2. Simple bar graphs or simple line graphs are remembered! Remember: SIMPLIFY, SIMPLIFY, SIMPLIFY!
3. Use few words and make one point per slide.
4. People can read faster than you can talk, so don't read numbers on charts. Just say, "The blue line shows…" or "The lower right box shows that this variable is the critical one."
5. Do not use cute pictures and animations on your PowerPoint slides. It distracts! This is a talk for professionals, not middle school students. Of course if your talk is on one or two species, then show their pictures, and…
6. This does not mean not to use as the main point on a slide, a quirky cartoon, a pretty habitat slide, or a critical conclusion in one line (or add lines of conclusions, one after the other).
7. If you must use an acknowledgment slide, then keep it up for only a few seconds! Nobody can read it all anyway, everybody knows from the abstract that you have co-authors and intuitively know that you needed money and had friends helping you! So put the slide up if you must, 10 seconds only, and just say "I want to thank all these people" and then change the slide.

The Mike

1. If you can't project your voice (breathing and talking from your diaphragm, not your throat…go to a live play and watch and listen to the actors), THEN USE THE MIKE! THE MIKE IS YOUR FRIEND! MAKE LOVE TO THE MIKE!
   a. Put your mouth/head about 3" from the mike. Leave it there. Don't move away, just turn your head to see the screen, for a glance… you should know your slides in order.
   b. Move the mike only so that it is 3" from your mouth. Don't move it aside. Speak loud into the mike. If and only If you can project your voice, then you can move your head back to 12".
   c. If you have to ask the audience if they can hear you and half say no, believe them! Not those in the front row.
   d. OPEN YOUR MOUTH, ENUNCIATE YOUR WORDS!
2. Talk to your audience, not the mike, not the slides, not your notes… you should know your slides and notes by now. Remember: PRACTICE, PRACTICE, PRACTICE! It helps to practice in a quiet room, out loud, with nobody else in the room.

Comments

1. Not everything is due to climatic change!
2. People in the audience usually don't speak up when asking a question. If in the audience, SHOUT OUT YOUR QUESTION. If speaker, REPEAT THE QUESTION, so that the rest of the audience can know to what question you are responding.
3. You have 15 minutes. Don't give the audience an overly scholarly, overly data/table-laden talk that they will not remember. Instead go 1, 2, 3, 4, and sit down!

Conclusions

1. Stick to the Big Picture.
2. Define your goal and know your audience.
3. Teach.
4. Speak loud, even shout!
5. Make love to the mike.
6. Simplify, simplify, simplify.
7. PRACTICE! PRACTICE! PRACTICE!

Field Herpetology of the Southwest

Southwestern Research Station — 24 July–2 August, 2015

This 9-day course will introduce participants to an outstanding diversity of amphibians and reptiles of Arizona's Chiricahua Mountains and surrounding deserts.

Labs and lectures will focus on identification and ecology of herps. The majority of time will be spent in the field, hiking through low and high elevation habitat.

For more information about the course, contact Dawn Wilson. Ph: 520-558-2396; email: dwilson@amnh.org; http://research.amnh.org/swrs/herpetology-field-course

Interdisciplinary World Conference on Monitor Lizards

27–29 July 2015 at Phranakhon Rajabhat University, Bangkhen District, Bangkok, Thailand

The Interdisciplinary World Conference on Monitor Lizards will focus on the biology, ecology, natural history, and captive breeding of monitor lizards. For those interested in attending and those who have enquiries are encouraged to contact the conference organizers at: *monitor.conference.2015@gmail.com* to receive the latest information about the conference and accommodations. Manuscripts and posters are also to be submitted to this address.

Conference fee: Has not yet been determined at the time of this announcement, but it is planned to make it less expensive than comparable international conferences. The conference fee is tentatively planned to be US $200. Included with the conference fee is conference attendance, lunch along with coffee breaks on the days of the conference, and the welcome dinner on the first day of the conference. Also included with the conference fee is a copy of the conference proceedings to be published after the completion of the conference.

There are optional events that will be available to those attending the conference, such as a trip to the National Science Museum and Natural History Museum, Dusit Zoo to see an urban monitor population, and a two-day trip to Khao Yai National Park. The costs of optional events are not included with the conference fee.

Fourth and Final Update!

UNIVERSITY OF KANSAS SSAR MEETING

THURSDAY, JULY 30 – MONDAY, AUGUST 3, 2015

Society for the Study of Amphibians and Reptiles

co-sponsored by Partners in Amphibian and Reptile Conservation (PARC)

together with the herpetological societies of Kansas, Missouri, and Arkansas, the Center for North American Herpetology, *and the* International Society for the History and Bibliography of Herpetology

• For registration and full conference details, visit SSAR2015.ku.edu •

Transportation, Parking and Housing

The Kansas City International Airport is one hour northeast of Lawrence. Shuttle options include vans. See list at www.flykci.com/direction/shuttle/Index.htm.

Ample free parking within a 3-block radius of conference activities will be available in surrounding university lots and nearby streets.

A wide variety of housing options are available ranging from low-cost dormitory rooms that can be shared to local hotels and motels. Options include:

- Springhill Suites by Marriott (downtown)
- The Oread Hotel (1 block away): $149–169
- Holidome (2 miles away): $80 for up to four people including breakfast
- On-campus dormitory housing: $40–$60

•

Registration Fees (Deadline June 30th)

Student members*	US $160
Regular members	$295
Seniors (retired / over 70) (membership not required)	$160
Non-members	$375
Late surcharge for all after June 30	$50

*For this meeting, student members of SSAR, HL, ASIH, and other international, national, and regional herpetological societies are eligible for the SSAR student member rate, but they must provide written evidence of their membership (statement from society officer, student's advisor, or other authority).

•

Deadlines for Presenters (May 15th)

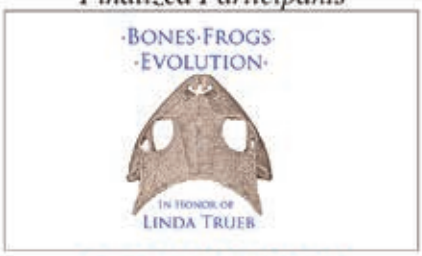
Abstracts for all papers (oral and poster) are due to the conference organizer by May 15th. These should include title, author or authors, and address (both postal and email). Full details on format for abstracts and posters as well as available projection facilities may be found on the SSAR 2015 meeting website: SSAR2015.ku.edu.

•

Meeting website (available March 15)

Visit SSAR2015.ku.edu for the day-by-day meeting schedule, registration, airport shuttle, parking, accommodations, meals, special events, tours, juried prizes, auction donations, committee meetings, socials and other activities associated with this meeting.

SSAR will hold its 2015 meeting on the beautiful and centrally located campus of the University of Kansas in Lawrence. All scientific sessions will be held in the Kansas Union, which is adjacent to the KU Biodiversity Institute and Natural History Museum, the setting of more than a century of research and graduate education in herpetology. The intimate campus setting will facilitate personal and friendly interactions while moderating fees for registration and lodging.



This unique campus format meeting will include oral and poster presentations, silent and live auctions, vendor displays, student social, symposia, and special lectures provided by David Hillis (Keynote), Harry W. Greene (Plenary), and Miguel Vences (President's Travelogue).

Conference activity highlights include:

- Redesigned audiovisual shows arranged by David Dennis and Eric Juterbock
- Reception honoring distinguished senior herpetologists, allowing students to interact personally with luminaries in the field
- The Herpetological Quiz, arranged by the graduate students at UT Arlington and KU, with prizes for winners
- Guided tours of herpetological collections and newly renovated laboratories in the Biodiversity Institute
- Tour of the Fitch Reservation (*see photo on next page*) at the KU Biological Fieldstation and Reserves, led by George Pisani
- Special presentation for the International Society for the History and Bibliography of Herpetology featuring author Sally Haines of the KU Spencer Research Library
- Display of live Kansas herps with photographic set-ups

SYMPOSIA UPDATES

Finalized Participants

Bones, Frogs, and Evolution

Organized by David Blackburn, Anne Maglia, and David Cannatella

This event will celebrate the exceptionally productive 40 years of scholarship of Linda Trueb and will include presentations by Ana Maria Baez, David Blackburn, David Cannatella, Luis Coloma, Eli Greenbaum, Juan Guayasamin, Anne Maglia, Dave McLeod, Greg Pregill, Chris Sheil, Helio de Silva, Erik Wild, and Marvalee Wake. Introduction by Leonard Krishtalka and summary by William Duellman.

•

Frontiers in Integrative Organismal Biology: Herpetological Horizons

Organized by Rich Glor and Rafe Brown

This event will bring together a group of exceptionally research-active herpetologists working at the forefront of evolution-related fields, using amphibians and reptiles as study systems. Topics include speciation, adaptive radiation, convergence, phenotypic evolution, and the evolution of development—all through the lens of genomic approaches to understanding evolution of amphibians and reptiles. Participants include Frank Burbrink, Todd Castoe, Ben Evans, Matt Fujita, Luke Harmon, Ryan Kerney, Adam Leaché, Emily Lemmon, Jim McGuire, Rachael Mueller, Dan Rabosky, Erica Rosenblum, Robert Thompson, John Wiens, and Kelly Zamudio. Summary by David Wake.

continued on next page

continued from previous page

In 1979, SSAR premiered the first of four half-hour audiovisual shows featuring herps, herp habitats, and herpetologists, that became highly popular events at its annual meetings over the next 25 years. These shows have not been seen for ten years and have now been completely revised using high-definition Blue Ray technology. Most of the photography will be completely new. Two of these newly revised shows will debut at the KU meeting in 2015.

Meeting Agenda Highlights
full details at SSAR2015.ku.edu

Thursday, July 30
SSAR Board of Directors Meeting
Registration
Presidential Travelogue Lecture
Welcome Social for all

Friday, July 31
Poster sessions and concurrent papers
Plenary sessions
Keynote Lecture
Plenary Lecture
PARC symposium
Reception for all with distinguished senior herpetologists
AV shows

Saturday, August 1
Poster sessions and concurrent papers
SSAR and PARC symposia
SSAR student social
Live auction and reception for all

Sunday, August 2
Concurrent papers
PARC and SSAR symposia
SSAR business meeting
Outdoor picnic for all

Monday, August 3
Meetings and tours for the International Society for the History and Bibliography of Herpetology, plus day trips and tours

Kansas Biological Survey

PARC
PARTNERS IN AMPHIBIAN AND REPTILE CONSERVATION

PARC-SPONSORED EVENTS

PARC Symposium 1: Identifying Priority Areas for Herpetofauna Conservation
Organizer: Phillip deMaynadier
Moderators: Phillip deMaynadier and Bill Sutton
Confirmed speakers: Ron Sutherland, Phillip deMaynadier, J. J. Apodaca, Stephen Speare, Cyndy Loftin, Bill Sutton, Brian Todd, Kyle Barrett, Robin Moore, James Lewis, Stephen Mockford, Mike Jones, Liz Willey, Priya Nanjappa

PARC Symposium 2: PARC's Partners Focusing on Habitat
Organizer: Jen Williams
Moderators: Jen Williams, David Bender, John Moriarty
Confirmed speakers: Jason Daniels, Therese Conant, Joe Robb, Paul Makela, Mark Vandever, Jeff Holmes

PARC / SSAR Symposium 3: Communicating Herpetofaunal Conservation to the Public
Organizer and moderator: Linda Weir
Special speaker: Tyrone Hayes

PARC / SSAR Workshop: Distilling Your Message
Organizer: Linda Weir
Moderator: presenter from Alan Alda Center

PARC Event: Exploring Non-academic Careers in Herpetology: a lunch time event for students
Organizers: Danny Martin and John Moriarty

FEATURED SPEAKERS

KEYNOTE LECTURER

David Hillis
University of Texas at Austin
Evolutionary Insights from Studying Amphibians and Reptiles

PLENARY LECTURE

The Life and Times of a KU Herpetological Icon: Henry Fitch and 70 Years of Snake Ecology

PRESIDENTIAL LECTURER

Miguel Vences
Technical University of Braunschweig (Germany)
Inventory of an Imperiled Paradise: Two Decades of Herpetology in Madagascar

HERPETOLOGY AT KANSAS

A Centennial History

by William E. Duellman

THE UNIVERSITY OF KANSAS (KU) HAS long been recognized as one of the world's leading centers for research and education in herpetology. Beginning with the arrival of Edward H. Taylor as a student in 1908, KU has produced a steady stream of students—at both the undergraduate and graduate levels—who focused their work on amphibians and/or reptiles including studies in systematics, ecology, morphology, behavior, biogeography, evolution, and other subject areas. Their studies have been built around the broad-based research programs of the several professors involved: **Edward H. Taylor** and **Henry S. Fitch**, later **William E. Duellman** and **Linda Trueb**, and more recently **Rafe Brown** and **Richard Glor**.

This book chronicles the people—faculty and students alike—who have contributed to maintaining and expanding KU's herpetology program and details their lives, education, research, and fieldwork. The book also describes how a true institutional program, one that transcends individuals, was created and sustained over such a long period through innovative planning and social development. The extensive collections that these faculty and students made in many countries throughout the world are deposited in KU's Biodiversity Institute, which is located in Dyche Hall (*pictured*) on the central university campus. These comprise

one of the largest and most comprehensive museums of amphibians and reptiles in existence, now numbering in excess of 332,000 alcohol-preserved specimens, together with ancillary collections of osteological preparations, color images, frozen tissues, audio recordings, and the associated scientific literature. This book provides an insider's in-depth review of the many successes as well as plans that went awry or even courted disaster. It is **liberally illustrated with 440 photographs**. Altogether, the book represents a substantial and critical chapter in the history of the discipline of herpetology.

Specifications: about 350 pages, format 8.5 × 11 inches (21.5 × 28 cm), 440 photographs, index, clothbound. ISBN 978–0–916984–91–5. • ***To be issued June 2015.***

■ **Prices**: Pre-publication, SSAR members US$28; Institutions and non-members $40. ■ **Shipping**: USA address, add $5; non-USA, at cost. ■ **Send orders to:** SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, Utah 84158–0517, USA (*telephone and fax*: 801–562–2660; *e-mail*: ssar@herplit.com). ■ **Payment:** Make checks payable to "SSAR." Non-USA orders must be paid in USA funds using a check drawn on an American bank or by International Money Order. Books may be charged to American Express, Discover, MasterCard, or Visa (please give account number and expiration date). ■ **SSAR Membership and Other Publications:** Membership information and a list of society publications can be obtained from the Publications Secretary at the address given above or at the Society's website at www.ssarherps.org.

INFORMATION FOR CONTRIBUTORS

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes concerning the study of amphibians and reptiles, as well as book reviews, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (for information, please refer to: http://www.ssarherps.org/pages/JHinstr.php). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

http://ssarherps.org/publications/journals/herpetological-review/

REPRINTS AND PAGE PROOFS

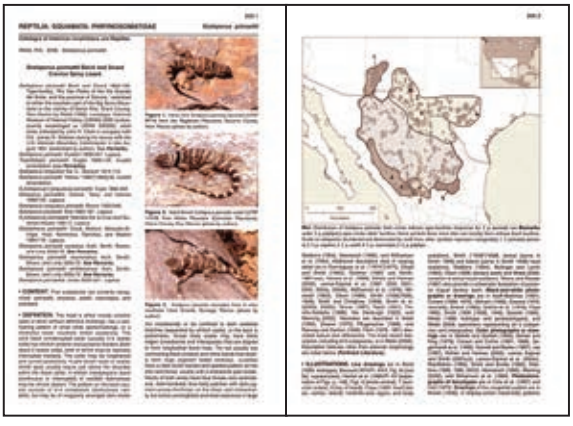
Page proofs are sent electronically to authors of all articles, book reviews, and obituaries, but are not prepared for natural history, geographic distribution, or herpetoculture notes. Proofs are sent as pdf files approximately 2–4 weeks prior to publication. High resolution electronic (pdf) reprints of notes, articles, book reviews, and obituaries are provided at no charge to the primary/corresponding author as a benefit of SSAR membership. Reprint files will normally be sent prior to the issue mailing date from the printer. Authors who are not current SSAR members may purchase pdf reprints from the SSAR Publications Office.

ADVERTISING

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pages/HRinfo.php).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at the Department of Natural Sciences, Williams Baptist College, P.O. Box 3692, Walnut Ridge, AR 72476, USA. Periodicals postage paid at Walnut Ridge, AR 72476 and at additional mailing offices.

All rights reserved. No part of this periodical may be reproduced without written permission of the Editor, except that authors and their agents are permitted to reproduce and distribute their own articles and notes.



POSTMASTER: Send address changes to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158. **MISSING OR DAMAGED ISSUE?** Please notify Breck Bartholomew, SSAR Publications Secretary (e-mail: ssar@herplit.com) for a replacement.

SSAR PUBLICATIONS

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive pre-publication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: http://www.ssarbooks.com/.

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

The *Catalogue* consists of individual accounts of species and genera prepared by specialists, including synonymy, definition, distribution map, and comprehensive list of literature for each taxon. The accounts cover amphibians and reptiles of the entire Western Hemisphere. As of 2014, SSAR is making all CAAR accounts OPEN ACCESS as a service to the herpetological community. To access individual accounts, visit http://www.ssarcaar.com.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology,* and its bulletin, *Herpetological Review,* both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review.*

To join SSAR or to renew your membership, please visit the secure online ZenScientist website via this link:
http://www.ssarherps.org/pages/membership.php

A New Report of Albinism in the Common Garter Snake (*Thamnophis sirtalis*), and a Review of Existing Records: Is There a Geographic Bias in Observations?

Albinism is one of the most striking aberrations of body color in vertebrates, arising from an absence of melanin in the integument (McCardle 2012). Errors at any of several steps in the pathway of melanosynthesis can block the production of melanin in the skin, largely (but not exclusively) as a result of autosomal recessive mutations (Bechtel 1995). In mammals, oculocutaneous albinism is associated with the expression of white skin and pale yellow hair due to a lack of accessory pigments in these structures (Bechtel 1995; Carden et al. 1998). In contrast, squamate reptiles normally possess additional classes of long-wavelength pigment in the integument expressed independently of melanin: pteridines, which are naturally produced in the dermis, and carotenoids, which must be acquired in the diet but may be secondarily stored in the dermis (Bechtel 1995). As a consequence, albino squamates that retain these accessory pigments typically exhibit yellow or red skin (xanthic albinism; "albino" sensu Bechtel 1995). The complete lack of endogenous integumentary pigment in squamates (i.e., no melanin or pteridine) is termed leucism, and the skin of leucistic reptiles is white (Bechtel 1995). Leucistic reptiles are also often referred to as albinos, especially in the older literature (McCardle 2012). However, xanthic albinos and axanthic albinos (i.e., leucistics) are phenotypically distinct, and the latter are especially uncommon (Bechtel 1991).

Reports of albinism in reptiles have been published on an occasional basis throughout the last century (e.g., Hensley 1959; Dyrkacz 1981 and references therein), but multiple records for an individual species remain the exception rather than the rule (Bechtel and Bechtel 1981; Krecsák 2008). The major reason is that albinos are rare: perhaps as few as 1 in 30,000 individuals in wild populations of a given species may exhibit the condition (Bechtel 1995). With the possible exception of species that inhabit aphotic environments (Gross et al. 2009; McCardle 2012), albinos are thought to experience reduced fitness relative to non-albino conspecifics, ensuring that the frequency of albinos remains low (Bechtel 1995; Krecsák 2008). At least partly as a consequence, reports of albinism are scarce for most individual species, limiting the potential to test hypotheses for the biological significance of albinism, and integumentary coloration more generally.

One exception to this generalization is the Common European Adder (*Vipera berus*). Krecsák (2008) found evidence that albinism in this widely distributed species was more common in the northern part of its range (i.e., Scandinavia) than in the south (central and southern Europe). Several possible explanations were invoked to explain this pattern: high local densities might provide protection to albinos by dilution effect; the reduced species diversity and population sizes of mammalian and avian snake predators at northern latitudes further reduce predation pressure on albinos; and offshore islands, the source of several specimens, may be linked to increased rates of albinism due to genetic drift mechanisms, inbreeding, or both (Krecsák 2008).

Another possible explanation is that populations at northern latitudes may be less vulnerable to negative effects of UV radiation, diminished at northern latitudes relative to the tropics. This hypothesis has been invoked to explain the reduction of integumentary melanin in human populations at northern latitudes as compared with those found near the equator (Jablonski and Chaplin 2010), but conceivably could help explain elevated frequencies of albinism at high latitudes in some other vertebrate groups. We note that some ectothermic organisms exhibit *increased* melanism in populations at higher latitudes, apparently as an adaptation for increased thermoregulatory efficiency (e.g., Clusella Trullas et al. 2007). This overall pattern, however, is not incompatible with relaxed selection on albinos via reduction in UV-induced skin damage.

The Common Garter Snake (*Thamnophis sirtalis*) is one of the most wide ranging reptiles in North America, found from Florida and southern Quebec in the east, to California and British Columbia in the west (Rossman et al. 1996). Isolated populations are known as far south as northern Mexico, and as far north as the Northwest Territories of Canada. The latter populations represent the most northerly known for any snake in the Western Hemisphere (Rossman et al. 1996). Twelve subspecies are presently recognized in this taxon, of which the most widely distributed is the Eastern Garter Snake, *T. s. sirtalis* (Rossman et al. 1996).

In April 2013, a female albino Eastern Garter Snake *T. s. sirtalis* was discovered by one of us (KMD) in a residential neighborhood in Macon, Georgia, USA. Following this discovery, we reviewed existing reports of albinism in natural populations of *T. sirtalis*

and other species of *Thamnophis* (Hensley 1959; Gilboa and Dowling 1974; Dyrkacz 1981). In light of Krecsák's (2008) study, and the exceptionally broad latitudinal distribution of *T. sirtalis*, we asked whether albinism in *T. sirtalis* also varies along a latitudinal gradient. We also considered whether observations of aberrant snakes vary along a longitudinal gradient. Given the diversity of eastern and western habitats utilized by this species in North America (e.g., subtropical marshland, montane forest, prairie, oak savannah: see Rossman et al. 1996) and the variable thermal, lighting, and predator-prey regimes experienced across these populations, it is conceivable that selection against albinos might be variable along an east-west gradient, independent of any possible north-south cline.

In this report, we first provide details on the newly discovered albino specimen of *T. s. sirtalis*. We then review existing published reports and museum specimens of albinos and leucistic *T. sirtalis* and other species of *Thamnophis*, and conduct statistical tests of the hypothesis that albinism and leucism vary geographically in *T. s. sirtalis*. We also provide perspective on the opportunities and challenges that await researchers interested in testing hypotheses for the functional significance of albinism in *T. sirtalis* and other reptiles.

MATERIALS AND METHODS

On 27 April 2013, KMD captured a female albino *T. s. sirtalis* (Fig. 1) in the backyard of his residence in Macon, Bibb Co., Georgia (32.85°N, 83.66°E) around 1200 h. This urban environment is an older, well-established neighborhood where most of the houses were built before 1915. The weather was mostly sunny with a temperature of about 20°C; however, the immediate surroundings where the specimen was found remain shady and moist most of the time (KMD, pers. obs.). The snake was discovered when, upon approach, it quickly retreated to a narrow space between a loose pile of red bricks and the wood paneling of the side of the house where it was collected. The appearance of this specimen coincided with other observations of snakes in the immediate area, probably a function of the onset of the spring breeding season in this species (Reed and Gibbons 2008). After capture, the snake was placed in a dark, cool environment until morphometric data could be collected two days later.

We then conducted a review of existing records of albinism and leucism in both *T. sirtalis* (Table 1) and other *Thamnophis* species (Table 2), limiting our search to records described in published reports, as well as searches of museum specimen databases provided in HerpNet2 (www.herpnet2.org). We list only those reports where at least state- or province-level locality data was provided; when subspecies was not given, we tentatively assigned putative subspecies using range maps in Rossman et al. (1996). We did not personally examine any preserved material; in many cases, final disposition of the described specimen(s) was not indicated in the original report. In this report, we use the definitions of Bechtel (1995) and restrict the terms "albino" to amelanistic xanthic specimens, and "leucistic" to amelanistic axanthic specimens. We note that the term "albino" has been applied by various authors to include a wider or narrower range of aberrant phenotypes (e.g., Harris 1970). Thus, it is conceivable that some listed specimens might not represent albinism as defined here (sensu Bechtel 1995).

To test whether the distribution of albino *T. sirtalis* differed from those of non-mutant (putative wild-type) *T. sirtalis*, we also searched HerpNet2 for all records of *T. sirtalis* specifically, including those listed under older genera (*Eutaenia* and *Natrix*). Of a total of 25979 records of this species, 9823 included latitude and longitude data, and were thus available for use in analysis. As HerpNet2 provides fields for entry of significant notes regarding specimens (such as the occurrence of albinism), we assumed that albinism would ordinarily be noted if it was present. Promisingly, we found one record (MSUM 183) in HerpNet2 described as albino that confirmed a literature report (Hensley 1959). However, we also found three records of albinism in the literature that were not described as such in their HerpNet2 specimen records (AMNH 162456, Hensley 1959; CM 48368, Dyrkacz 1981; CM 26259, Barton 1947). Thus, it is likely that some other specimens given in HerpNet2, but lacking supporting literature documentation, and which we assumed were wild-type in our analysis are in fact albino or leucistic. Prior to analysis, two of three records of albinos found in the literature but not described as such in HerpNet2 were removed to prevent their duplicative use in analysis; the third such record did not contain latitude and longitude data in HerpNet2 and therefore was not listed twice in the analyzed data set. One additional record of a putative wild-type *T. sirtalis* had clearly questionable locality data associated with it, and was also removed. We used nonparametric tests, as data for wild-type and albino *T. sirtalis* did not meet conditions for normality. All statistical analyses were conducted using Systat 12 (Systat Software, Inc. 2007).

RESULTS

Albino T. s. sirtalis *from Macon, Georgia.*—Measurements of this specimen were obtained on 29 April, two days after collection. At that time its body mass was 25.5 g, and its total length was 410 mm. Consistent with earlier reports of albino (sensu Bechtel 1995) *T. s. sirtalis*, this specimen exhibits a generalized yellow ground color with orange-red and blue-

TABLE 1. Reports of Common Garter Snakes (*Thamnophis sirtalis*) exhibiting albinism or leucism obtained through literature and museum database searches. Only records where state- (U.S.) or province-level (Canada) locality information was available are listed. An asterisk (*) indicates records where no subspecies assignment was given in the original publication or online museum database record, and is inferred from the geographic range of subspecies of *T. sirtalis* given in Rossman et al. (1996). Morph is indicated only when the source description(s) of the specimen provides sufficient information to suggest either albinism or leucism specifically. Multiple specimens from the same observation are indicated in parentheses under Age Class.

lavender color elements arranged in stripes; thus, the overall body color pattern is retained despite the absence of melanin. Scale rows 1–3 are uniform light yellow. Rows 4–8 are orange, with pale blue or lavender rectangular spots on rows 4 and 8 arranged in an alternating checkerboard pattern. A central yellow stripe occupies scale row 9. The ventral scales are a light yellow cream color. The distal portion of the tail exhibits a pronounced sinusoidal kink, suggesting a previous injury.

Albinism and leucism in T. sirtalis.—Including the specimen described here, we found 43 independent observations describing 52 cases of putative albinism or leucism in *T. sirtalis* (Table 1). Three observations described the birth of multiple albino offspring (Dyrkacz 1981; Weller 1983). Most of the original literature reports describing cases of albinism in *T. sirtalis* do not clarify whether a given specimen was specifically albino or leucistic (sensu Bechtel 1995). In 19 of these 43 cases, this distinction was clearly made in the original report, or could reasonably be inferred based on details of description of the specimen (see Table 1). Of these, only 3/19 individuals (16%) were reported to be leucistic, consistent with expectations that this phenotype is much rarer than albinism (sensu Bechtel 1995).

Of these 43 separate observations of aberrant Common Garter Snakes, at least 37 (88%) are definitely or probably the nominate subspecies *T. s. sirtalis*. Either albinism or leucism was reported in only 3 of 11 described subspecies (*sirtalis*, *parietalis*, and *pickeringii*) recognized by Rossman et al. (1996). Two of these (*sirtalis* and *parietalis*) represent the forms with the widest geographic range of any subspecies of Common Garter Snake, and their disproportionate representation among observations of albinism is therefore not unexpected.

Albinism and leucism in other Thamnophis.—We also examined reports of albinism in other species of garter snakes. Overall, we found 16 independent observations representing at least six species of *Thamnophis* exclusive of *T. sirtalis* (Table 2). In 13/16 records, albinism or leucism was specifically noted, and/or a distinction could be made based on a description of the reported specimen(s). Of these 13 specimens, only 1 (8%) was leucistic, again reinforcing the expectation that leucism (sensu Bechtel 1995) is a much rarer phenomenon than albinism in garter snakes more generally.

Geographical variation in albinism.—Inspection of Table 1 suggests that more putative albinos and leucistics have been found in areas towards the northern part of its range. Figure 2A graphically represents this trend, revealing a peak in the number of independent observations around 40°N latitude. However, we found no difference in the latitude of records of albino/leucistic snakes as compared with records of putative wild-type snakes (Mann-Whitney $U = 203269$; $P = 0.91$; albinos/leucistics: $\bar{X} = 41.0$°N, wild-type: $\bar{X} = 41.2$°N). The latitudinal distribution of putative wild-type snakes from the HerpNet2 database (data not shown) exhibits the same general pattern as that observed for albinos/leucistics, supporting the notion that the peak observed in Fig. 2A reflects biased sampling of *T. sirtalis* more generally.

The longitudinal distribution (Fig. 2B) reveals a central peak around -80°E longitude (i.e., from South Carolina to Ontario), though the paucity of records from much of the central and western part of the range of *T. sirtalis* may be problematic (Rossman et al. 1996). Nevertheless, there was a difference in the longitude associated with records of albinos/leucistics as compared with putative wild-type snakes (Mann-Whitney $U = 271642$; $P = 0.0001$); specifically, aberrant snakes were more

TABLE 2. Reports of albinism or leucism in species of *Thamnophis* exclusive of *T. sirtalis* obtained through literature and museum database searches. Only records where state- (U.S.), province- (Canada), or district-level (Belize) locality information was available are listed. An asterisk (*) indicates records where no species assignment was given in the original source. Morph is indicated only when the source description(s) of the specimen provides sufficient information to suggest either albinism or leucism specifically. Multiple specimens from the same observation are indicated in parentheses under Age Class.

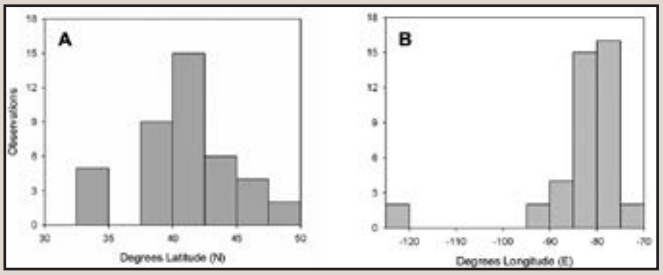

FIG. 2. Frequency histograms of unique observations of albinism and leucism in Common Garter Snakes (*Thamnophis sirtalis)* per degrees North latitude (A) and degrees East longitude (B). The latitude and longitude of each observation site were inferred from details of known site locality in the original source publication or museum description, and assessed using Google Earth. Where only county-level information was provided in the original description, we estimated the site latitude as an arithmetic mean of the most northerly and southerly latitudes associated with the geographical boundaries of each county. Two observations where at least county-level locality data were unavailable were excluded.

commonly reported from the eastern US (albinos/leucistics: $\overline{X}$ = -83.1°E), whereas the mean longitude of records of wild-type specimens was shifted further west (wild-type: $\overline{X}$ = -97.9°E).

We did not perform statistical analysis on the smaller data set of aberrant garter snakes of *Thamnophis* species exclusive of *T. sirtalis* (Table 2),; however, we note that a majority of observations were also found at sites around 40°N latitude.

DISCUSSION

Albino T. s. sirtalis *from Macon, Georgia.*—According to Carpenter (1952), sexual maturity in *T. s. sirtalis* may be attained at a snout-vent length (SVL) around 400 mm. Although we did not measure SVL at the time of capture, populations of *T. s. sirtalis* in Michigan have tails that comprise about 25% of the total length. Assuming that Georgia populations of *T. s. sirtalis* have similar growth patterns, by extrapolating an SVL of ~ 300 cm at the time of collection we interpret that the individual was a subadult when captured, probably born the previous spring or summer (Carpenter 1952). We acknowledge, however, that geographic variation in life history traits in *T. sirtalis* is extensive (Rossman et al. 1996), and growth rates in populations from Georgia might differ from those in Michigan. Interestingly, a snake strongly resembling the specimen described here was seen about two weeks prior to this observation in the same area of the Drace residence (KMD, pers. obs.), suggesting that the same snake may have been resident in the area for at least a few weeks. Although the possibility that it was a separate specimen should not be discounted (e.g., Dyrkacz 1981), we know of no other reports of putative albino snakes from the area.

Albinism in subspecies of T. sirtalis.—Although *T. sirtalis* contains at least 11 described subspecies, albinism has been only reported in just three subspecies, two of which (*sirtalis* and *parietalis*) have the largest geographic ranges of the species. Is albinism less common in subspecies of *T. sirtalis* where it has not yet been reported? Several lines of evidence suggest that this is probably not the case. First, many subspecies of *T. sirtalis* for which albinism has not been recorded have small geographic ranges (Rossman et al. 1996), and several occur in relatively remote areas of western North America. Thus, albinism may be less likely to be encountered in some of these populations, simply because of difficulties in accessing appropriate habitat. In addition, population bottlenecks and associated inbreeding can generate an increase in homozygous recessive traits such as albinism (e.g., Gilhen et al. 2012). As a consequence, some isolated populations of *T. sirtalis* may be subject to higher rates of albinism than those seen elsewhere. Finally, it is also likely, in our view, that some relatively recent observations of albinism in this species have not been published, perhaps due in part to a lack of perceived scientific interest in additional observations. Although this is conjectural, we note that the most recent published report we found for albinism in any population of Common Garter Snake was that of Smith (1997).

Geographical variation in albinism.—We considered whether records of albinism and leucism in *T. sirtalis* indicated a geographic bias to the distribution of albinos and leucistics in this species, as has been described in *V. berus* (Krecsák 2008). A strong test of this hypothesis would compare the frequencies of aberrant snakes in multiple populations across the geographic range of *T. sirtalis,* and test whether these frequencies differ across a latitudinal or longitudinal gradient. Such an approach is not feasible at the present time; the number of records of albinism and leucism we found was too small (Table 1) to generate reliable calculations of aberrant morph frequencies per population (or even per museum). Instead, we simply compared the latitude and longitude of albinos to those of wild-type snakes from a search of museum records. This approach has its own drawbacks: for example, it assumes wild-type specimens are collected or observed at a given locality in direct proportion to their frequency in natural populations, and that albino specimens would be noted as such in HerpNet2, which is clearly not always the case. Nevertheless, this approach offers, in our view, a reasonable starting point to address this question.

All else being equal, we expected that if albinos are encountered at higher frequencies in the northern part of their range as compared with elsewhere—assuming that any such observation bias corresponds to true differences in the frequency of albinism—we would find that the number of observations of albinos was skewed in this direction. The peak number of observations was centered at around 40º N (Fig. 1A), roughly the central part of their latitudinal range (Rossman et al. 1996). However, there was no difference in the median latitude of albinos and wild-type snakes, and the distribution of wild-type snakes in the HerpNet2 database corresponds closely with that of albinos. Thus, we find no support for the hypothesis of a latitudinal gradient of albinism per se, though limited sampling in the northern and southern parts of its range could conceivably obscure a real pattern. It is also conceivable that albinos are more strongly selected against at relatively high and low latitudes, and are more abundant at around 40ºN, but distinguishing between this possibility and observer bias is not presently possible.

The peak distribution of albino and leucistic *T. sirtalis* was centered around -80ºE, with two observations much further west (Fig. 2A). There was a difference in the median longitude of albinos and wild-type snakes, with putative wild-type snakes found further west than albinos. Common Garter Snakes are largely absent from the major deserts of the western and southwestern US (Rossman et al. 1996), and the comparatively small number of records in HerpNet2 of *T. sirtalis* found at sites between the Great Plains and western Nevada found is not unexpected (data not shown). However, it is notable that we found no records for albino *T. sirtalis* from California specifically, despite the large number of records from that state with latitude/

longitude data in the HerpNet2 database (2293/9823 specimens from California, or 23% of the total).

Summary and future directions.—Is there a geographic bias in the occurrence of albino *T. sirtalis*? We found no evidence for a latitudinal bias in observations, but did find evidence of a possible longitudinal bias. If this pattern reflects a real biological phenomenon, perhaps the paucity of albino *T. sirtalis* records from the west reflects underlying differences in thermal, climatic, or predator regimes in western habitats, as compared with those elsewhere in its range.

We caution, however, that there are many possible alternative explanations for this pattern. For example, a small observation/collection rate of albinos at sites in the west might reflect local behavioral plasticity; as one possibility, adoption of crepuscular or nocturnal activity by albinos could conceivably lower detection rates at a given site, even if the frequency of albinos is unchanged. Alternatively, perhaps the majority of western specimens have been collected under study designs that either advertently or inadvertently tended to minimize the chance of encountering (or capturing) aberrant snakes. In addition to collection or observer bias, perhaps museums holding the majority of western specimens of *T. sirtalis* tended to omit supplemental information about a given specimen (such as possible color anomalies) when data were uploaded to HerpNet2. This possibility underscores the importance of direct inspection of individual specimens whenever possible (Krecsák 2008).

Determining which of these factors, if any, is responsible for the limited number of observations of aberrant *T. sirtalis* in the western part of its range represents a significant challenge. However, testing the hypothesis of a longitudinal (or latitudinal) bias might be more feasible in the context of a larger cross-species study. As a possible starting point, we note that albinism has been reported from at least four species of garter snake that have ranges that extend into California (*T. sirtalis*, *T. elegans*, *T. marcianus*, *T. ordinoides*, Tables 1–2; Rossman et al. 1996), but for which we found no confirmation of albinism from any record within that state, either within the literature or in the HerpNet2 database.

More generally, data on color aberrancies from studies of Common Garter Snakes in the north, south and western parts of the range of *T. sirtalis* are needed to provide a better sense of whether the apparent absence of albinos from these areas has a real biological basis. Inspection of individual preserved snakes is also likely to reveal additional specimens not reported here. It is also possible that some reports describing "albinism" in *T. sirtalis* conflated albinism (sensu Bechtel 1995) with other color aberrancies, and inspection of older preserved specimens to confirm and/or reassess aberrant color status is recommended for future studies. Despite the limitations inherent in the approach described here, we believe that we have made steps towards a rigorous analysis of geographic variation in albinism and its possible functional significance.

Acknowledgments.—We thank the Georgia Department of Natural Resources for granting permission to collect the snake for research and display purposes (permit # 29-WJH-13-74). John B. Jensen of Georgia DNR confirmed the specimen as *T. s. sirtalis*. We gratefully acknowledge the following individuals for their efforts in helping locate missing museum specimens: Dave Cicimurri (South Carolina State Museum), Scott Pfaff (Riverbanks Zoo), Charles Smith (Wofford College), Kyle Schuett, Gordon Schuett (Copperhead Institute), and Thomas Pauley (West Virginia Biological Survey). Two anonymous reviewers provided comments that greatly improved the manuscript. The Department of Biology at Mercer University provided logistical and financial support for this report. Herpetological specimen data used in this study were obtained from the California Academy of Sciences, San Francisco; Carnegie Museum of Natural History, Pittsburgh; Cincinnati Museum of Natural History; Cornell University Museum of Vertebrates; Savannah Science Museum Herpetology Collection, Georgia Southern University; University of Kansas Biodiversity Institute; Los Angeles County Museum of Natural History; Museum of Comparative Zoology, Harvard University; Milwaukee Public Museum; Museum of Southwestern Biology; Museum of Vertebrate Zoology, University of California, Berkeley; Slater Museum of Natural History, University of Puget Sound; Redpath Museum, McGill University; Royal Ontario Museum, Toronto; Santa Barbara Museum of Natural History; San Diego Natural History Museum; Staatliches Museum für Naturkunde, Stuttgart; University of Alberta Museums, Edmonton; Beaty Biodiversity Museum, University of British Columbia; Museum of Natural History, University of Colorado; University of Nevada, Reno; National Museum of Natural History, Smithsonian Institution, Washington, D.C.; Burke Museum of Natural History and Culture, University of Washington; Peabody Museum of Natural History, Yale University. Results of Repeated Surveys for the Brazos Water Snake (*Nerodia harteri*) in a Section of the Brazos River in North Texas

The Brazos Water Snake, *Nerodia harteri*, is a medium-sized, semiaquatic snake known from the Brazos River drainage of Texas (Werler and Dixon 2000; Gibbons and Dorcas 2004). *Nerodia harteri*, along with its sister species that was previously considered conspecific, *N. paucimaculata* of the Concho and Colorado River drainages, are the only two snake taxa endemic to Texas. Both are considered to be riffle habitat specialists, especially as juveniles (Werler and Dixon 2000; Gibbons and Dorcas 2004). It is thought that *N. harteri* hunts mostly fish in riffles and that this habitat is critical to the successful feeding strategy of juveniles. *Nerodia paucimaculata* has been the focus of numerous studies, and was previously listed by the United States Fish and Wildlife Service (USFWS) as threatened (Whiting et al. 2008). Populations of *N. paucimaculata* have been monitored and stabilized, and the species has been delisted by the USFWS. Comparatively little work has been done on *N. harteri*, so we attempted to survey for the presence of the species in a section of the Brazos River where it was historically considered abundant to obtain an estimate of local population size and genetic diversity.

Materials and methods.—An approximately 32 km-long section of the Brazos River was surveyed approximately monthly for the presence of *Nerodia harteri*. This section of river extended from Texas State Highway 16 in the west to Texas State Highway 4 in the east and was chosen for several reasons, but most importantly, it contains the type locality for *N. harteri*. Scott et al. (1989) found *N. harteri* in our study area at the highest density for any stretch of the Brazos River of comparable length. For our surveys, the river was split into two sections nearly equal in length. Surveys were always two days long and both sections of the survey route were run in the same calendar month for consistency. Surveys were run sporadically, but not more than once per month between April and October, the general active season for *N. harteri*. Survey activities consisted of canoeing or kayaking the river and looking for snakes basking or swimming. We also stopped at all likely cover objects (logs, large single rocks) and riffle areas to flip cover objects and visually search for snakes. These are commonly used survey techniques for river-dwelling snakes (Whiting et al. 2008; McBride 2009). When a snake of any

TABLE 1. Schedule of snake surveys and counts of snakes observed.

TABLE 2. Collection data for individuals of *Nerodia harteri* captured during this study. CT = cloacal temperature; TOC = time of capture.

	Sex	Mass (g)	SVL (cm)	TL (cm)	CT (°C)	TOC	Date
N. harteri #1	Male	7	21.5	29	18.9	0840 h	20 September 2011
N. harteri #2	Female	13.5	26	34	20.6	0908 h	20 September 2011

species was located, we attempted to move closer to positively identify it to species or capture it. We collected the following data from captured snakes: geographic location (marked by GPS point), physical location and behavior (e.g., under rock, swimming across river, etc.), time of capture, sex (S), snout–vent length (SVL), total length (TL), mass (M), cloacal body temperature (CT). Unique scale clip patterns taken from ventral scales were used to mark individual juvenile snakes for identification in case of recapture. Scale clips were stored dry in marked small plastic bags as tissue samples for DNA analysis. Snakes were then released at the physical point of capture. Adults were to be marked with PIT (passive integrated transponder) tags, but no adult *N. harteri* were located in the course of this study.

Results.—We encountered at least 39 individuals of six species of snakes during our surveys from June 2011 to October 2013 (Table 1). Table 1 shows when surveys were run and the counts of each species encountered during surveys. Exact numbers of *N. erythrogaster* and *N. rhombifer* could not be determined because we could not get close enough to several snakes to make a positive identification (listed as "unidentified *Nerodia*") and some snakes were encountered while basking in contact with each other, which made counting the exact number of individual snakes difficult. We did not presume that any individual unidentified *Nerodia* were *N. harteri*. Table 2 shows the data collected for both individuals of *N. harteri* captured during our surveys, excluding geographic location and physical location of each individual at the time of capture. For conservation related reasons, we have chosen not to reveal the physical locations of collected individual *N. harteri* in print, but will provide that information to those who request it for scientific use.

Discussion.—We encountered many problems with our study design. All planned surveys were not run because of numerous funding and weather related factors. We began surveys at approximately the same time in the morning. This meant we surveyed areas closer to our put in point earlier in the day at cooler temperatures repeatedly. This also means we surveyed portions of the survey route farther from the put in point later in the day during generally hotter temperatures. Snakes were generally easier to locate during the warmest parts of the day early and late in the year and during the early morning hours during the heat of the summer. These factors almost certainly influenced our number of snake encounters. Water conditions varied greatly based on water releases from the Morris Sheppard Dam, holding back Possum Kingdom Lake. During periods of relative high water, most riffle areas on the river were inundated, leaving few rocks and cover objects for us to flip while searching for snakes. This is a proven method for locating both adults and juveniles of *N. harteri*, but was not possible during high water. In light of these limitations, we do not include a rate of catch per unit effort for snakes encountered during our surveys, as we feel these data are unreliable.

Despite these limitations, a number of snakes were located during surveys. However, as show in the results, only two *N. harteri* were captured. Both of these individuals were neonates located under different small rocks on the edge of the same riffle on the same survey day. Based on their different body sizes and geographic locations in the riffle, it is likely they were not from the same litter. We feel that even though our study design had practical limitations, we should have encountered more individuals of *N. harteri* if a reasonably large population

existed in this stretch of river. We originally intended to perform a mark/recapture study and population genetic analysis on *N. harteri* in our study area. This was not possible because of the extremely low number of initial captures and the complete lack of recaptures. We do speculate that *N. harteri* is now very rare in at least the section of the river we surveyed and it may be difficult to accurately assess population size (Krebs 1989).

Anecdotal reports (T. Hibbitts and A. Price, pers. comm.), along with collection records (Trapido 1941; Maxwell 1982; Dorcas and Mendelson 1991; Rossi and Rossi 1999; McBride2009; Rodriguez 2012), and one very thorough survey (Scott et al. 1989) suggest that before approximately 1995 *N. harteri* was not difficult to find in and near our study area. The causes for the apparent decline of *N. harteri* in our study area are probably multifactorial, but may include habitat alteration from both changes in hydrology (McBride 2009) and invasive species (Blackburn et al. 1982; Brotherson and Field 1987). Specifically, during periods of hydroelectric power generation, the Morris Sheppard Dam typically released large amounts of water nearly every afternoon during the summer, creating an unnatural flow regime (McBride 2009). Regarding invasive species, we have noticed an increase in the amount of saltcedar (*Tamarix ramosissima*) from both historical levels as determined by photographs and through our own observations over the course of this project. Scott et al. (1989) also commented on the ability of saltcedar to impact the river ecosystem. Scott et al. (1989) suggests that they considered *N. harteri* to be "relatively secure." We found a very low number of *N. harteri* during the course of our surveys and do not agree that within our survey area populations of *N. harteri* are secure. Based on our results, we recommend more studies be done on the current range wide occupancy of *N. harteri* within its historic range. We also recommend once remaining populations of the snake are located, that efforts are made to quantify the population size of snakes in that location.

Acknowledgments.—We thank the keeper staff of the Fort Worth Zoo Department of Ectotherms, the Wildlife Division of the Texas Parks and Wildlife Department, D. McBride, and D. Card for their assistance with fieldwork and/or technical assistance with this project. We thank L. McCoy, T. and T. Royer for river access and logistical support. We thank the Texas Parks and Wildlife Department's Horned Lizard License Plate Fund for funding. All research was conducted under the University of Texas at Arlington's Institutional Animal Care and Use Protocol #A07.021.

Body Size and Growth of the Eastern Collared Lizard *(Crotaphytus collaris)* in Central Arkansas

The Eastern Collared Lizard (*Crotaphytus collaris*; Fig. 1) is a saxicolous species inhabiting warm, arid habitats common to the southwestern United States (Templeton et al. 2001). Arkansas and Missouri represent the eastern range limit of *C. collaris* (Templeton et al. 1990) where this species is restricted to exposed bedrock (glades) and rocky outcrops within the Ozark and Ouachita mountains (Trauth et al. 2004). Historically, Ozark landscapes were maintained by natural and anthropogenic fire regimes (Strausberg and Hough 1997; Van Lear et al. 2004). However, wildfires were suppressed in the Ozarks throughout the 20th century (Fralish 2004; Verble 2012) which allowed invasion of fire-intolerant plant species into glade habitats (e.g., Eastern Red Cedar, *Juniperus virginiana*), and provided conditions for succession of other woody plant flora (Brisson et al. 2003; Van Zandt et al. 2005). Dense vegetation in glade habitats is correlated with delayed age of maturity, reduced growth rates and adult body size, shortened activity seasons (Sexton et al. 1992), and limited population size and gene flow (Brisson et al. 2003; Templeton et al. 2011) in *C. collaris*. The evidence is compelling that changes in plant assemblages of glade habitats is linked with population declines of *C. collaris* in the Ozark Mountains.

Habitat fragmentation and continued population declines prompted the Arkansas Game and Fish Commission to list *C. collaris* as vulnerable in Arkansas (Anderson 2006). Grimsley (2012) found that of 20 sites where *C. collaris* were documented in the 1970s (Trauth 1974), they persisted at only eight sites three decades later. Remaining populations are geographically isolated, with little opportunity for migration among sites. Because small, isolated populations are at the greatest risk of extirpation, understanding population dynamics of *C. collaris* in the state is vital to conservation and management of the species. However, few data on life history parameters or demographics are available for Arkansas populations since the most recent wave of extirpations (Trauth 2011; Grimsley 2012).

In Arkansas and Missouri, yearling *C. collaris* must attain a minimum SVL of ~77 mm to reproduce in their first full activity season (males 76 mm, Trauth 1979; females 77 mm, Sexton et al. 1992). Similarly, clutch size is positively correlated with body size of adult female *C. collaris* (Trauth 1978; Ballinger and Hipp 1985). Because fecundity is a major component of population dynamics (Gadgil and Bossert 1970; Shine and Scwarzkopf 1992; Dunham and Overall 1994), and body size is linked to fecundity, it follows that age-specific body size and growth are appropriate indicators of the health of *C. collaris* populations.

Research in Missouri demonstrated statistical differences among size and growth (SVL) of *C. collaris* from a single study site (Sandy Ridge, Missouri) when compared across two time periods, one before fire suppression (1960–1965) and the second after fires were suppressed and the habitat was invaded by fire intolerant vegetation (1975–1988; Sexton et al. 1992). Sexton et al (1992) reasoned that the marked difference in size and growth of *C. collaris* between time intervals at Sandy Ridge was due to habitat degradation associated with fire suppression over the later time interval, and Brewster et al. (2013) provided an explanation for how the changing habitat structure could affect growth of individuals in this species.

There are limited published data on body size or growth rates of *C. collaris* in Arkansas (but see unpublished thesis with unreported sample size; Trauth 1974). Thus, the objective of this study was to document the body size and growth of a *C. collaris* population in central Arkansas as a potential baseline for long-term monitoring and comparisons with other populations in the state. To assess the current status of the central Arkansas population, we compared body size and growth data from the central Arkansas population to the Sandy Ridge, Missouri population both post suppression (presumed degraded habitat) and pre suppression (presumed undegraded habitat) of fire.

Materials and Methods.—We performed this study on a privately owned rock quarry near Scranton (Arkansas River Valley ecoregion) in central Arkansas that contains 4–5 adjacent colonies of *C. collaris* interspersed within an area of ~170 ha. Although we found no evidence of migration between the two most spatially separated colonies (~950 m), migration between adjacent colonies is fairly unimpeded (all sites are connected by open dirt roads and corridors of grassland). Thus, for the purpose of this study, we treat all colonies at this site as one population. The majority of the site consists of large areas of exposed bedrock

and boulder piles, with sparse vegetation interspersed within a prairie-savanna matrix with ~1-m tall grasses and intermittent hardwood forest.

We captured lizards by hand or by noose between May and October 2011. We visited the site three to five times per month for a total of 19 collecting trips. Upon capture, we recorded SVL to the nearest mm, sex, and age class. We palpated the abdomen of females to determine reproductive condition. We did not attempt to distinguish sex of hatchling lizards. The time and date of capture, and any unique scars or wounds were noted. After initial capture, we gave each lizard a unique individual toe-clip to permit future identification (Huey et al. 1990). We also marked lizards with a paint pen (small dot on the back of the head) to distinguish them from un-captured individuals, and released all individuals at their location of capture. Consistent with recommendations for wild taxa (Sikes et al. 2012), our methods followed taxon-specific guidelines approved by the American Society of Ichthyologists and Herpetologists for the use of wild amphibians and reptiles in research (Beaupre et al. 2004).

We were unable to distinguish between adult age classes (i.e., 2-year-olds from 3-year-olds) in this one-year study. However, differences in size and coloration allowed delineation of hatchlings, yearlings (sub adults in their first full activity season), and adults (2-year-olds and older). To increase accuracy of yearling and adult delineation, we developed an equation using body size and age data available in the literature (Sexton et al. 1992; Brisson et al. 2003) to estimate a predicted maximum SVL of yearling lizards:

$$SVL_{max} = g_i * d_i + SVL_{init},$$

Where SVL_{max} is the maximum SVL of a lizard to be classified a yearling, g_i is the mean growth rate of other individuals in the yearling size class (0.22 mm/day), d_i is the Julian date of initial capture for that individual minus the Julian date of initial capture of first group of individuals in yearling size class (160), and SVL_{init} is the greatest SVL of initial group of yearlings captured (80 mm for females and 86 mm for males).

We did not attempt to determine sex of hatchlings, so to make comparisons of mean hatchling SVL between populations we combined sexes. Similarly, we combined all lizards over two years of age to compare mean SVL of adults across populations.

We compared individual growth rates of the central Arkansas population to those from Sandy Ridge post suppression (Sexton et al. 1992). To increase sample size of individual growth rate comparisons of Sandy Ridge post suppression, we combined sexes (0 and 1 year olds did not differ significantly between sexes). Statistical comparisons of individual growth rates of Sandy Ridge pre suppression were not possible due to sample size.

Raw data for the Sandy Ridge pre and post suppression (Sexton et al. 1992) were not available, so we were limited to comparisons using the mean, standard deviation, and sample size for each size/age class. We conducted T-tests (SAS 9.2, 2011) to test for differences in mean body size and growth, within each age class, between populations. We used the pooled standard deviation when classes were combined (Zar 1999). To assess sample sizes used in growth comparisons, we provide the least significant number (LSN; Zar 1999). We use Cohen's *d* (estimate of effect size) with 1- = 0.80 and = 0.05 to calculate LSN (Cohen 1992).

Results.—We recorded a total of 141 captures of 42 yearlings and adults, and 77 captures of 37 hatchlings over the course of the study. We recaptured 76% of adults and yearlings, and 42% of hatchlings at least once.

Body size was similar for all age/size classes between the central Arkansas population and Sandy Ridge pre suppression (Table 1). Except for adult females, body size tended to be larger in the central Arkansas population than lizards from Sandy Ridge post suppression (Table 1).

Sexton et al. (1992) concluded that yearling females must reach a minimum SVL of 77 mm by June 1 to oviposit eggs during their first full activity season. Six of the eight yearling females in the central Arkansas population attained a minimum SVL of 77 mm before June 1. Although we could not verify reproduction, we detected follicles (by palpation) in all but the two smallest yearling females.

Growth rates did not differ significantly between the central Arkansas population and Sandy Ridge post suppression. Five of the seven classes used to test for growth differences were represented by sample sizes of 10 individuals or fewer in the central Arkansas population, so the lack of statistical differences might be due to small sample size. We provide the LSN to assess the impact of small sample size in growth comparisons (Table 2).

Discussion.—The mean body size of *C. collaris* from central Arkansas compares favorably with Sandy Ridge pre suppression. Data for most of the age classes suggest that *C. collaris* in the central Arkansas population are significantly larger than individuals from Sandy Ridge post suppression and do not differ

TABLE 2. T-test analysis of mean growth rates by age and size class between central Arkansas and Sandy Ridge, Missouri 1975–88 (Post suppression; Sexton et al. 1992). Rate represents growth (mm/day) in SVL, standard deviation (SD), sample size (N), t statistic (t), p value (P), and estimated minimum sample size to detect a significant difference (LSN).

in size from *C. collaris* at Sandy Ridge pre suppression. Although individual growth rates of *C. collaris* from central Arkansas were not significantly greater than growth rates of lizards at Sandy Ridge post suppression (in all but 55 mm SVL or less), the LSN of these classes suggests that sample sizes were simply too small to provide a robust test for statistical differences. A summary of mean growth rates from four other populations (Table 3) suggests that the central Arkansas population is intermediate to high with respect to body growth.

Data on yearling female body size and growth suggest that potential annual fecundity of the central Arkansas yearling females should be relatively high. Six of the eight yearling females (75%) in the central Arkansas population reached the predicted minimum body size (77 mm SVL) necessary for reproduction in their first full activity season. This is a substantial difference from the 46% and 23% of yearling females estimated to reach maturity at Sandy Ridge pre and post suppression, respectively. Further, mean body size of adult females was similar to those from Sandy Ridge pre suppression (Table 1). Thus, assuming a consistent correlation between body size and fecundity, per capita fecundity may be similar between the central Arkansas population and that of Sandy Ridge pre suppression.

This study has provided growth and body size estimates to characterize the status of a central Arkansas population of *C. collaris*. In general, our results suggest that this is a relatively healthy population (compared to other Ozark populations), and provides a suitable baseline for future monitoring of *C. collaris* populations in Arkansas. It is important to point out that population vital rate estimates, such as survival, recruitment and population growth rate are the true proxies of population health (Case and Roughgarden 2000). However, because it is the interaction of life history parameters and population dynamics that ultimately dictates populations (Dunham et al. 1989), combining body size and growth estimates with population vital rate estimates provides a more comprehensive and powerful tool to assessing population status of *C. collaris* in Arkansas. Thus, to monitor and develop effective conservation strategies for *C. collaris* populations in Arkansas, data from other populations are needed.

Acknowledgments.—We thank the landowners for allowing us access to the *C. collaris* population. This study would not have been possible without their generosity and patience on our many visits to their facilities. We thank Timothy Clay, Nicholas Whitten, Cody Barnes, Melissa Rogalla, Jonathan Gray, and the rest of the UALR volunteers who helped in the field throughout the study. We also thank J. D. Willson for constructive comments that significantly improved the manuscript. This research was supported financially by the University of Arkansas at Little Rock and approved by the Institutional Animal Care and Use Committee (protocols: R-11-03 and R-10-01).

Pattern-Recognition Software as a Supplemental Method of Identifying Individual Eastern Box Turtles *(Terrapene c. carolina)*

Identifying and monitoring individuals is essential in behavioral and ecological studies of wild animals. Traditional methods for permanently marking turtles include shell notching, tagging with aluminum bands, and insertion of passive integrated transponder (PIT) tags (reviewed in Ferner 2007 and Plummer and Ferner 2012). These methods have been shown to be effective, but applying such marking techniques may result in increased stress, altered behavior, or opportunities for infection (McGregor and Peake 1998; Markowitz et al. 2003; Fisher 2007). Therefore, it is desirable to use methods of long-term identification that minimize the potential impact on the organism.

As technology improves, researchers have taken advantage of photographing naturally occurring or conspicuous marks to identify individuals (reviewed in Reisser et al. 2008 and Bolger et al. 2012). Traditionally, pattern-recognition involved comparing hard copies of photographs against catalogues of photographs to identify recaptures. In the case of large image catalogues, the number of images makes pattern-matching a time-consuming process and increases the probability of visual errors (Hammond et al. 1990; Katonas and Beard 1990; Sears et al. 1990; Gamble et al. 2008).

Shell patterns have been suggested to be a viable means of identifying individual box turtles (Budischak et al. 2006; Wynn and Moody 2006; Weiss 2009; D. E. Hoss, pers. comm. 2013). Photo-recognition techniques offer several advantages such as reduced handling time of the animal, an increase in the efficiency of identifying individuals, and elimination of the problems associated with loss of tags or other artificial marks (Reisser et al. 2008). In addition, pattern recognition is inexpensive, less invasive than most of the traditional methods of permanently marking turtles, and lessens the chance of identity failure due to wear or malfunction. As such, pattern-recognition software has the potential to be a cost-effective alternative method of identifying box turtles.

At our study site in northwestern Ohio, USA, the required method of marking Eastern Box Turtles (*Terrapene carolina carolina*) is use of PIT tags. The expense of using PIT tags and the readers required to confirm the presence of a PIT tag can quickly eat away at the small grants available to fund local mark-recapture studies. Additionally, this method of marking carries the extra complication of making it impossible to identify recaptures without a PIT tag reader. To aid in future mark-recapture studies and to involve the public in local Eastern Box Turtle conservation efforts, we sought to use digital photography to supplement our use of PIT tags. The goals of our project were to: 1) test pattern recognition as a viable method of identifying individual Eastern Box Turtles; 2) to determining if top-down carapace, off-center carapace, or plastron photos were more diagnostic; and 3) to test the ability of a pattern recognition program to identify individuals from different populations.

Methods.—We collected photographs of Eastern Box Turtles from three areas in two states: the Oak Openings Region (OOR) of northwestern Ohio (41.556°N, 83.854°W) from 2004–2013, Ft. Custer Training Center (FCTC) and the adjacent Ft. Custer Recreation Area (FCRA) in Michigan's southwestern Lower Peninsula (42.324°N, 85.298°W) in 2005 and from 2011–2013, and the Manistee National Forest (MNF; 43.875°N, 85.914°W) from 2009–2013. The impetus for obtaining images from multiple states was to determine whether or not images from different locations would result in false matches. Upon capture, top-down pictures were taken of the turtle's carapace and plastron (N = 610 of each; Ohio = 170; FCTC/FCRA = 307; MNF = 133). Additionally, we used a subset of images (194) taken without standardizing (i.e., pictures taken from any angle; hereafter "off-center") to compare the efficacy of these two methods. A minimum bounding rectangle that reduced the amount of visible background present was used to crop each image. The pictures from all locations were combined into carapace, off-center,

and plastron categories within an image database. Turtles with a plastron length less than 7.0 cm were not used because their shell patterns do not appear to be fully developed (D. E. Hoss, pers. comm. 2013).

To identify individual Eastern Box Turtles in our study, we employed the relatively new pattern-recognition software Wild-ID(http://www.dartmouth.edu/~envs/faculty/bolger.html; Bolger et al. 2012). Wild-ID is stand-alone, open-source, multi-platform software that uses Java to implement pattern-recognition. The Wild-ID software uses a Scale Invariant Feature Transform Operator (SIFT; Lowe 2004) to find and extract distinctive features invariant to the scale, rotation, viewpoint, local distortion, and illumination of the image. The geometric arrangements of these SIFT features for each pair of images in the dataset are compared to one another. The program then calculates the goodness-of-fit between the images and assigns a matching score (values range from 0.0000 to 1.0000, where values closer to 1.0000 indicate a stronger match). A full description of these steps can be found in Bolger et al. (2012).

Once Wild-ID has completed the above steps, the user interface displays each focal image along with 20 of the top-ranked images (Figs. 1 and 2). This allows the user to assess the images visually and based on matching scores to conclude whether or not the focal image has a match. Once matching scores were assigned, we used the Kruskal-Wallis procedure and *post hoc* Mann-Whitney U-tests in R (R Development Core Team 2011) to compare carapace, off-center, and plastron matching scores. For this project, a correct response from Wild-ID was recorded if: 1) a successful recapture was identified and 2) if no mismatches between individuals or sites occurred. The individual marking techniques used at the study sites (PIT tags in the OOR; shell notches at FCTC/FCRA and MNF) were used to verify the matches reported by Wild-ID.

Results.—Mean (± SE) recapture matching scores for carapace, off-center, and plastron images were 0.1918 ± 0.0266 for carapace, 0.0396 ± 0.0111 for off-center, and 0.1813 ± 0.0373 for plastron. In no case was the highest-ranked image a different turtle if it was a recapture. Additionally, Wild-ID did not erroneously match images between sampling locations or states and verified recaptures, as confirmed by shell-notching and PIT tagging, at each location. Results of the Kruskal-Wallis tests indicated that there was a significant difference between matching scores of the three image categories ($\chi^2 = 59.91$, df = 2, $P < 0.0001$); *post hoc* tests indicated that there were significant differences in matching scores between carapace and off-center ($P < 0.0001$) and plastron and off-center ($P < 0.0001$), but not between carapace and plastron ($P = 0.6492$).

Discussion.—Overall, Wild-ID performed ideally for identifying Eastern Box Turtle recaptures from carapace and plastron images, but exhibited lower efficacy when off-center images were used. We initially expected plastron images to be less accurate because the plastron occasionally lacks distinguishing patterns (MDC, pers. observ.), but there was no statistical difference between the plastral and carapace images. Plastron images were correctly matched just as often as carapace images and what little pattern may be present was sufficient for the program to identify a match. Because this method has not been tested before with Eastern Box Turtles, we wanted to make sure the program would not mismatch turtles from Ohio with turtles from Michigan; we found no mismatches, suggesting that Wild-ID is in fact suitable for identifying individual adult Eastern Box Turtles from their shell patterns.

Wild-ID represents a cost- and time-effective method of identifying individual eastern box turtles for mark-recapture studies. However, this is not to say that this should be the only means of identifying turtles. For long-lived species like Eastern Box Turtles, whose patterns do not fully develop until later on in life, photo-recognition software alone may not be sufficient for life-long identification and should still be coupled with an additional marking technique until the long-term validity of computer-assisted pattern-recognition has been verified. Additionally, shell damage is a potential source of error, especially in the case of burn scars where a large portion of the shell may be rendered patternless. Photographic mark recapture relies on three conditions: 1) individuals can be photographed, 2) individuals bear some phenotypic pattern variation that easily identifies them from other individuals, 3) an individual's pattern does not vary through time (Bolger et al. 2012). The unique patterns of Eastern Box Turtle shells lend themselves to this method with the exception of the criterion that the pattern remains unchanged.

Many turtles in our study had visible carapace imperfections that appeared to be the result of fires, mower blades, cars, or general wear. Shell damage may influence the results of programs such as Wild-ID, but as we saw with several of our turtles, as long as a majority of the pattern remained, Wild-ID could identify the image as a match. While carapace injuries and subsequent pattern alterations are relatively common, we observed that the plastron pattern remained relatively unchanged in most individuals. Whereas carapace images have been suggested as the minimum requirement to identify a turtle (Wynn and Moody 2006), based on our results, we strongly suggest photographing the plastron as a secondary form of identification, particularly in the case of individuals with damaged carapaces.

Although Wild-ID surpassed our expectations for pattern-recognition with Eastern Box Turtles, we noted that there are a number of ways future studies can improve the probability of the program identifying a positive match. We identified soil and glare on the turtle's shell and amount of background as potential factors contributing to lower matching scores. We recommend that turtles be photographed on a uniform background (e.g., a blank piece of paper) in an area that reduces the amount of glare and shadow on the shell and that soil be cleaned from the shell prior to image-capture. Similarly, for studies specifically seeking to accurately record recaptures, we recommend using cameras with the same resolution. Glare, patterns marred with soil, and images with a disparity in resolution can all lead to reduced matching scores. The SIFT operator, however, will still work with whatever pattern is present in the image (D. Bolger, pers. comm. 2013). Standardizing the method of image-capture in the manner we suggest should lead to increased matching scores, but is not necessary and will depend on the goals of the study. For instance, if the goal of the project is to reduce the amount of handling, off-center photos could be used as long as photos are taken from approximately the same angle. Again, as there is currently no way to confirm a correct identification prior to the development of a pattern on the shell, this method should be considered a supplement to traditional marking techniques.

We encourage researchers and naturalists who have taken photographs of Eastern Box Turtles in the past to utilize this software as a means of rapidly analyzing historical photographs to identify recaptured individuals. This sort of recognition software, combined with citizen-science programs (e.g., Davidson College Herpetology Laboratory's Box Turtle Mark-Recapture Program; Hester et al. 2008), could provide the means for mark-recapture studies of Eastern Box Turtles over a large geographic range.

Acknowledgments.—Funding and support for this project were provided by Bowling Green State University, the Toledo Zoo, the Metroparks of the Toledo Area, and the Michigan DNR. We thank A. Ihnken, T. Swem, S. Bristow, E. Cannarile, H. Tripp, O. Stacey, K. Klein, J. Forward, C. Schuttler, K. Akright, N. Birmingham, E. Cipolla, L. Liehr, L. Wisnieski, M.Archer, and C. Lucas, who gathered data in the field, as well as the numerous people who called in turtle sightings and sent us pictures, especially the staff of the Metroparks of the Toledo Area and members of the Toledo Naturalist's Association. Special thanks go to D. Bolger, S. Pelini, and B. Adams for their assistance and advice. All turtles in this study were handled in compliance with guidelines set forth by Bowling Green State University's IACUC and the Michigan and Ohio Departments of Natural Resources.

An Update to a Bead-Tagging Method for Marking Lizards

Most lizard species lack natural marks, thus impairing our ability to identify individuals by means of visual cues, a prerequisite for many behavioral and ecological studies. Thus, it is often necessary to mark individuals. Toe-clipping (e.g., Waichman 1992) has been a frequently used method to mark lizards, although alternative techniques are often necessary (see Ferner 2007).

The negative impacts of the amputation of lizards' digits is debatable (Paulissen and Meyer 2000; Langkilde and Shine 2006; Grafe et al. 2011); notwithstanding this, toe-clipping has the major disadvantage of not permitting identification at distance and can be an unreliable marking system as lizards frequently lose their toes due to agonistic interactions or when struggling to escape from predators (Passos et al. 2013). Thus, other methods such as implanting of passive integrated transponders—PIT tags—is also advocated to mark lizards (Smyth and Nebel 2013). However, PIT tagging may impair locomotion (Le Galliard et al. 2011) and be stressful (Langkilde and Shine 2006) for lizards; additionally PIT tags cannot be read at distances greater than two meters. Another method used to mark reptiles is the implant of visible elastomers (Schmidt and Schawarzkopf 2010; Waudby and Petit 2011), but despite its advantage of being ethically acceptable this method has relatively high costs. Thus, in many cases, researchers have to rely on other methods to mark individual lizards. Some authors have marked animals with nontoxic ink dots on the lizard's skin (Van Sluys 1997); however, the durability of this technique is relatively short, especially as lizards undergo ecdysis.

Fisher and Muth (1989), hereafter referred to as "FM," developed a technique for permanently marking lizards that avoids the problem of mark loss during skin shedding while also making the mark visible at a distance. This technique involves the surgical attachment of colored beads at the base of the lizard's tail, allowing individuals to be identified by different combinations (i.e., codes) of colored beads. Many studies have used the FM procedure to mark lizards larger than 40 mm in body size (e.g., Martins 1991; Halloy and Robles 2002; Paterson 2002). However, when marking lizards smaller than 40 mm the use of "queen bee marking kits," that consist of cardboard dots coded with a combination of color and numbers that have to be glued to lizards (see Johnson 2005), is a short term alternative.

Since Fisher and Muth's (1989) method was described, new material associated with modern surgical techniques could provide a less harmful procedure for marking lizards. Herein we describe a bead-tagging method for permanently marking live lizards derived from that of FM.

We developed the present method using dead *Tropidurus torquatus* lizards (snout to vent length range ca. 70–130 mm) from the Herpetological Collection of the Natural Sciences Museum of the Pontifícia Universidade Católica de Minas Gerais. We used surgical 4-0 EP 1.5 sterile black nylon monofilament for skin closure (needle is manufactured already attached to monofilament) to attach up to three colored beads of 2.2 mm diameter × 1.6 mm length on the dorsum of the lizard's tail. After development of the method, and exhaustive tests with dead animals, we applied it in our studies of live animals as described below. As live individuals frequently struggle when being held, we found that marking should be done by two persons to minimize the stress of handling on the animals: one person should hold the animal, and the other person should perform the marking process, hereafter referred to as the marker.

The marking was done by following the surgical instrument tying technique to perform a series of the named square knots (Odland and Murakami 1994) to attach beads at the base of the lizard's tail. Thus, the surgical needle with the attached monofilament is inserted through the dorsolateral skin just behind the base of the lizard's tail (Fig. 1a, b). The needle with the monofilament should be introduced in a caudal–cranial (back to front) direction (Fig. 1a, b). Then, beads are attached to the monofilament by passing the non-needle end of the monofilament through each bead allowing ca. 6 cm of the free suture filament end to lie freely. Following FM, bead code is read front to back; thus, the last bead is strung on first to provide the correct reading sequence. To finish the procedure, the beads were secured with a series of the aforementioned surgical knot techniques as described below.

To firmly tie the monofilament with beads we held a forceps in our right hand perpendicular to the line of and below the needle end of the monofilament (Fig. 3a). Then, we triple-wrapped the needle end monofilament around the forceps in the direction away from the marker-person forming loops around the monofilament (Fig. 1c). Following this, we turned the tip of the forceps to the non-needle end and grasped it, then passed it through the suture loops (Fig. 1d). We tied the knot by moving the two monofilament parts in opposing directions (Fig. 1e; see arrows); at this point, tension has to be applied with both hands (Fig. 1e). In the next step the monofilament is wrapped around forceps in the opposite direction of previous knot (i.e., in the direction of the marker). Following this, this procedure is repeated four more times, always alternating the wrapping loops direction. At the end of procedures the needle-end part of the monofilament has to be cut off leaving ca. 5 mm of the monofilament free (Fig. 1f). We found that by having two persons working together, we could mark an individual lizard in ca. 90 seconds.

We have used the described method to mark five lizard species: *Tropidurus hispidus*, *T. montanus*, *T. semitaeniatus*, *T. torquatus*, and *Eurolophosaurus nanuzae*. In general, such *Tropidurus* species are heliophilous, diurnal, and medium-sized lizards (SVL ca. 70–110 mm). In the case of the Flat Lizard *T. semitaeniatus* a crevice specialist, we attached the beads laterally to avoid loss through abrasion within crevices. For the small-sized species *E. nanuzae* (adult SVL ca. 55 mm), we opted to use a thin (2.0 EP) monofilament and only up to two beads. During

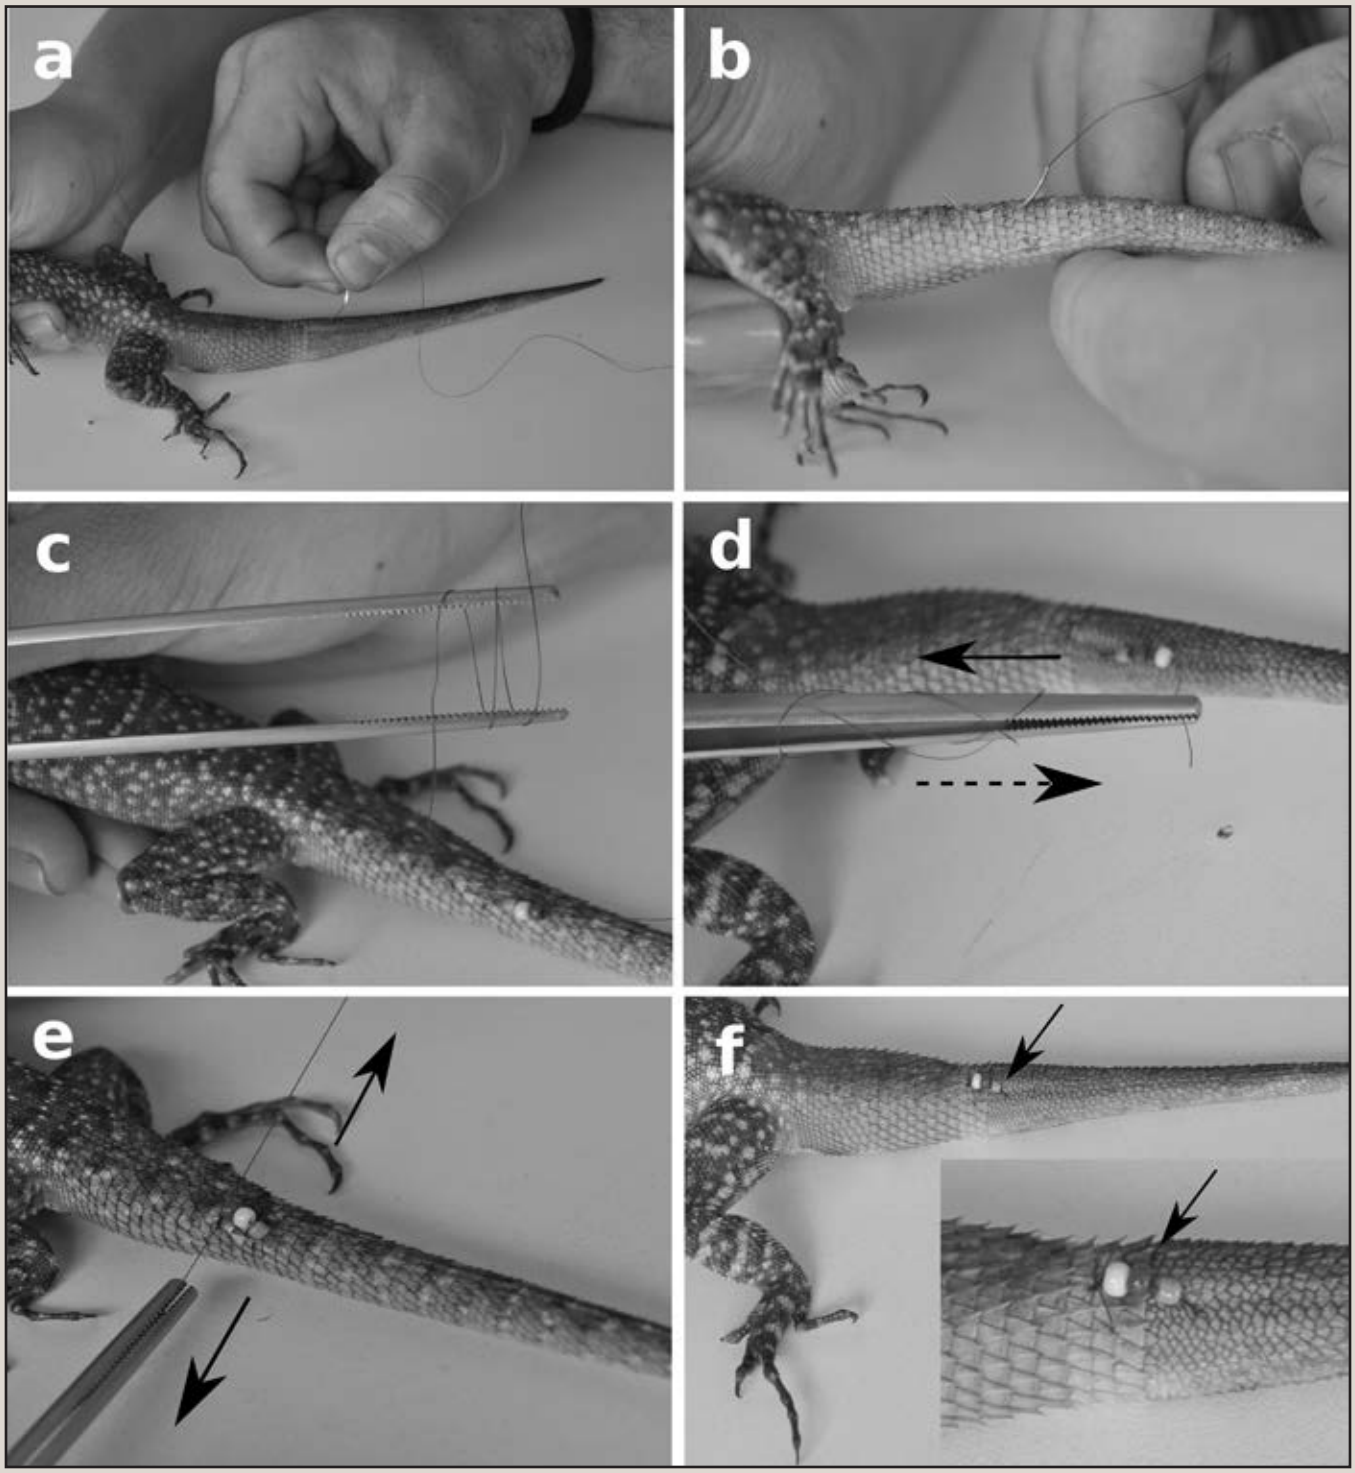

FIG. 1. Procedure to mark lizards through beads attached to tail: a) and b) insertion of the needle with the monofilament in a lizard's tail; c) triple-wrap loops of the monofilament around forceps; d) forceps with loops around grasping monofilament no-needle end, arrows represents the direction that forceps (continuous arrow) and the non-needle end of monofilament (dashed arrow) should be pulled; e) tightening the knot by pulling monofilament parts in opposing direction (arrows); f) manner in which monofilament must be cut off to finish the procedures of bead tagging method for marking lizards.

our studies on the behavior and space use of the aforementioned species, we observed no injuries or necrosis in marked animals. Furthermore, lizards did not seem to lose tail functionality as marked lizards were seen performing tail displays such as "tail extend" and "tail raise" (*sensu* Carpenter and Ferguson 1977). In our behavioral studies, marked lizards were observed to bask normally, forage, and perform assertive head bob displays. No abnormal behavior was observed.

Overall, our modification of the bead-tagging method for lizards developed by Fisher and Muth (1989) had clear

animal welfare benefits over the original method. The nylon monofilament we used had an attached skin closure needle that eliminates the necessity to pierce through the lizard's tail (from the ventral to the dorsum), which in turn should reduce the chance of causing harm to a marked male's hemipenis, its retractor muscle, and its lymphatic chamber, a risk mentioned by FM in their original paper. Moreover, our method reduced the number of needle insertions, reducing by half the number of potential infection points. Thus, welfare gains should outweigh the costs due to the need of two persons to perform markings as required by the technique we presented.

Our marking method, as per the original FM method, appeared not to affect an individual's behavior. After being marked, lizards were seen executing behaviors that were observed in free-ranging non-marked individuals, and no injuries, loss of tail, or necrosis were observed. The method we present is simple to perform and less harmful to lizards. However, as did Fisher and Muth (1989), we advise that those using our method for the first time practice this procedure on dead individuals or artificial models before using it on live lizards.

In summary, the modifications we propose in the FM technique reduce the number of body perforations points and permit the use of a smaller body perforation. Thus, we recommend it to researchers and animal caregivers who need long-term marking solutions.

Factors Affecting the Accuracy and Precision of Triangulated Radio Telemetry Locations of Eastern Indigo Snakes *(Drymarchon couperi)*

Radio telemetry (i.e., very high frequency or VHF telemetry) has proven an invaluable tool in understanding snake ecology because researchers can locate a telemetered snake virtually at will, thereby obtaining a relatively unbiased view of its behavior and movements (Reinert 1992; Beaupre and Duvall 1998). Researchers generally use homing techniques (Mech 1983) to obtain a visual location of a telemetered snake or its retreat site. As a result, a researcher can obtain very accurate geographic coordinates of the snake's location where accuracy is limited by the resolution and detail of field maps or aerial photos or the accuracy of a GPS unit. In contrast, many studies of mammals or birds use triangulation to estimate the locations of telemetered animals. Triangulation consists of taking directional bearings at two or more locations and then using the intersections of those bearings to estimate the animal's location (White and Garrott 1990). Triangulation introduces additional error to location estimates and the degree of error depends on many factors including the distance between the transmitter and receiver, the orientation or height of the transmitter, topography, vegetation structure, animal behavior, signal interference, or inter-observer variability (Lee et al. 1985; Garrott et al. 1986; Schmutz and White 1990; White and Garrott 1990; Townsend et al. 2007; Bartolommei et al. 2012). These errors may have significant implications for subsequent analyses of space use and resource selection.

Situations may arise where triangulation is necessary to obtain location estimates for telemetered snakes. For example, an individual may move onto property a researcher cannot access, into a large extent of flooded habitat, or into impenetrably thick vegetation. While triangulation may prove useful in these situations, triangulating telemetered snakes features several challenges. Snakes spend large amounts of time underground or in thick vegetation which may interfere with signal strength or direction. They often use the same retreat site for multiple days at a time as well as small-scale or linear habitat features (e.g., forest or wetland edges, Blouin-Demers and Weatherhead 2001; Pattishall and Cundall 2008) and this use may be difficult to detect using triangulated locations. Finally, many snake species spend the majority of their time close to the ground and the low vertical height of their transmitters can reduce triangulation accuracy (Townsend et al. 2007). All of these factors could potentially reduce triangulation accuracy below the level required to adequately address a study's objectives (Samuel and Kenow 1992; Rettie and McLoughlin 1999; Montgomery et al. 2010, 2011). While triangulation is apparently rare in telemetry studies of snakes and other herpetofauna (but see Whiting and Miller 1998), when applied, it may be particularly critical to determine the accuracy of triangulated locations given the aforementioned challenges. However, we are unaware of any studies reporting on the accuracy of triangulated locations for snakes or the factors influencing their accuracy.

Multiple metrics are used to evaluate triangulation accuracy. Many studies report error polygons around estimated locations, such as a 95% confidence ellipse (e.g., Lenth 1981), as a measure of accuracy (Saltz 1994; Withey et al. 2001). However, these polygons provide a measure of precision, not accuracy per se, and field tests have shown that error polygons may not include the true transmitter location (Garrott et al. 1986; Nams and Boutin 1991; Withey et al. 2001). Determining accuracy requires beacon tests in the field using transmitters at known locations either attached to the study organism or placed at similar heights and orientations (Lee et al. 1985; Garrott et al. 1986). This allows a direct measurement of accuracy as either the distance between the estimated and true location (linear error), difference between bearings to the estimated and true location (angular error), or the proportion of true locations contained within an error polygon (coverage, Garrott et al. 1986; White and Garrott 1990). Because the factors influencing accuracy might differ among studies due to study-specific factors, such as study site characteristics, transmitter size, or inter-observer variability, it is necessary that researchers conduct beacon tests prior to each study under the conditions present at their study site (Withey et al. 2001).

We conducted a radio telemetry study of Eastern Indigo Snakes (*Drymarchon couperi*) as part of a movement and resource selection study. During our study, multiple telemetered snakes moved onto private lands where we were unable to obtain access from the landowner. During these instances, we used standard triangulation techniques to estimate the locations of our telemetered snakes. To determine the accuracy and precision of the triangulated locations, we conducted a series of beacon tests using known locations of telemetered snakes. In this paper, we report the accuracy and precision of our beacon tests and the effects of different factors on triangulation accuracy (i.e., linear error). We also compared two different statistical estimators commonly used to estimate triangulated locations, Andrew's estimator (AE) and Lenth's maximum likelihood estimator (MLE, Lenth 1981). Finally, we developed a multiple regression model based on our beacon tests to predict linear error for locations estimated by triangulation and identify locations which met predefined criteria for accuracy based on the spatial resolution of our environmental data.

Materials and Methods

Study area and species.—We conducted on our study on the southern 40 km of the Lake Wales Ridge in Highlands County, Florida, USA (27.21°N, 81.33°W). Our study area was a mix of natural habitats (scrub, scrubby flatwoods, mesic flatwoods,

TABLE 1. Summary statistics from beacon tests and triangulated locations for Eastern Indigo Snakes (*Drymarchon couperi*). Results are presented for Lenth's maximum likelihood (MLE) and Andrew's estimators (AE, Lenth 1981). Estimated distance is the distance from the observer to the estimated location averaged across all bearings for a given location, ellipse area is the size of the 95% confidence ellipse, predicted linear error is the distance between the true and estimated location predicted by the model-averaged parameter estimates from the multiple regression analysis of the beacon test data, and true linear error is the actual distance between the true and estimated location.

forested and non-forested wetlands), cattle ranches, citrus groves, and rural and urban development. We searched for Eastern Indigo Snakes using road-cruising and visual encounter surveys around Gopher Tortoise (*Gopherus polyphemus*) burrows, although 90% of captures were made opportunistically while tracking other snakes or travelling among field sites. We selected snakes to receive radio transmitters depending on their capture location in order to distribute snakes as evenly as possible throughout our study area. We transported these snakes in large plastic boxes (30.3 L, 50.5 × 35.8 × 30.7 cm) to the Small Animal Hospital at the University of Florida, Gainesville, Florida, for transmitter implantation. We used 9 and 13.5 g SI-2T temperature sensitive transmitters (Holohil Systems Ltd., Carp, Ontario, Canada) with smaller snakes generally receiving the smaller transmitters. Transmitters did not exceed 2% of a snake's body mass. Anesthesia and surgical procedures followed those of Reinert and Cundall (1982) and Hyslop et al. (2009). Once snakes were fully alert and recovered from anesthesia we transported them back to Highlands County and held them in large (121.9 × 147.3 × 45.7 cm), well ventilated terrariums. Snakes were held for 48–72 h after surgery except during cold periods (highs < 25°C and lows < 14°C) in Nov.–Feb. when we held each snake for 7–14 days after surgery (Hyslop et al. 2009) to facilitate healing of the incision. In these instances, snakes were released once the forecasted highs and lows for the next five days were > 25° and > 14°C, respectively. Each telemetered Eastern Indigo Snake was released into the closest burrow or brush pile to its capture location.

Field data collection.—We located each telemetered Eastern Indigo Snake a median of every two days (range 1–60) using a three element Yagi antenna and a R-1000 receiver (Communications Specialists, Inc., Orange, California). We conducted beacon tests in a haphazard manner throughout our study on telemetered snakes whose location we were able to access and which did not appear to be moving on the surface based on their transmitter signal. To conduct the beacon tests, an observer would take a set (3–5) of bearings from known locations towards the telemetered snake's location (recorded with a GPSmap 76CSx, Garmin International Inc., Olathe, Kansas, mean accuracy = 7 m) and then immediately use homing techniques to locate the snake and record its actual location. The observers deliberately varied their distance to the snake, the number of bearings used, the angle between bearings (keeping the angle between the two most extreme bearings < 160°), and the surrounding vegetation conditions in a haphazard manner. This allowed us to understand how triangulation accuracy varied under a range of conditions. When a telemetered snake was on property we could not access at the time, the observer would also take 3–5 bearings towards the snake's location. Our goal in these cases was to maximize the accuracy of the estimated location so the observer tried to get as close to the snake as possible, generally used three or four bearings (depending on the configuration of the property), and maintain an angle of 60–120° between the outermost bearings.

Triangulation.—We used LOAS 4.0 (Ecological Software Solutions LLC, Hegymagas, Hungary) to estimate triangulated locations and 95% confidence ellipses with both AE and MLE. We found that some sets of bearings (i.e., the 3–5 bearings taken for each location) contained apparent outliers which did not intersect the rest of the bearings in the set or were markedly divergent from the other bearings. Because factors such as signal reflectance, polarization, background noise, or observer error may lead to erroneous bearings, even those taken from identical locations (Lee et al. 1985), one must decide at what level this error becomes detrimental to the ultimate goal of obtaining accurate location estimates. Other studies have excluded bearings or triangulated locations based on the angle of the bearing or the size of the error ellipse (Lee et al. 1985; Marzluff et al. 1997; Van Etten et al. 2007). After examining our data, we found that an angular difference between the bearing taken in the field and the bearing to the estimated location (estimated using either AE or MLE) > 20° represented what we felt were outlying bearings. Subsequent examination confirmed that such bearings did not intersect the other bearings in the set or were strongly divergent. We removed outlying bearings from both beacon tests and triangulated locations using the same criterion to maximize the applicability of our predictive model.

Accuracy and precision.—Our primary measure of accuracy for the beacon tests was linear error which was determined by

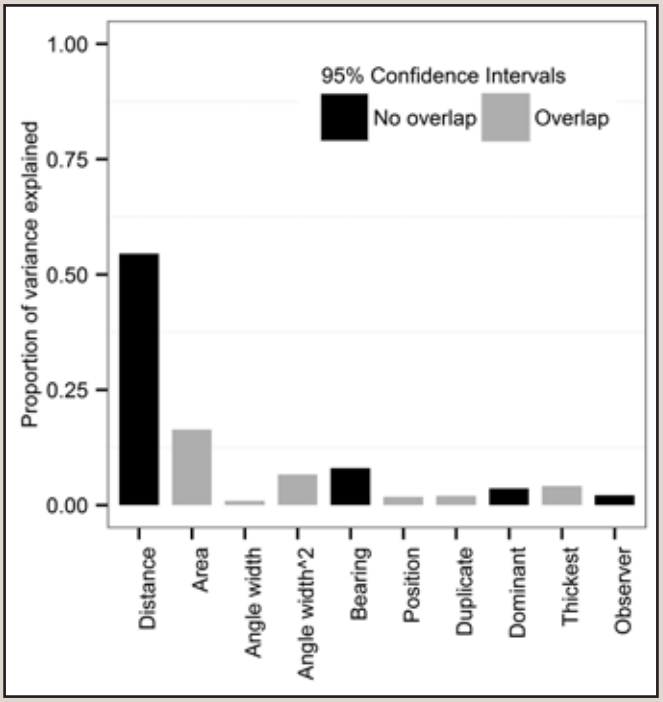

FIG. 1. Proportion of independently explained variance in linear error between true locations and estimated locations estimated using Lenth's maximum likelihood estimator (MLE) from Eastern Indigo Snake *(Drymarchon couperi)* beacon tests (N = 60). Predictor variables are distance to estimated location (Distance), size of error ellipse (Area), angle between the two outermost bearings (Angle width and Angle width^2), number of bearings (Bearing), position of the snake (Position), whether or not the snake was at a previously used location (Duplicate), dominant (Dominant) and thickest (Thickest) vegetation class traversed by the bearings for a given location, and observer (Observer). Dark shaded bars represent variables or levels (categorical variables) whose model-averaged 95% confidence intervals did not overlap zero.

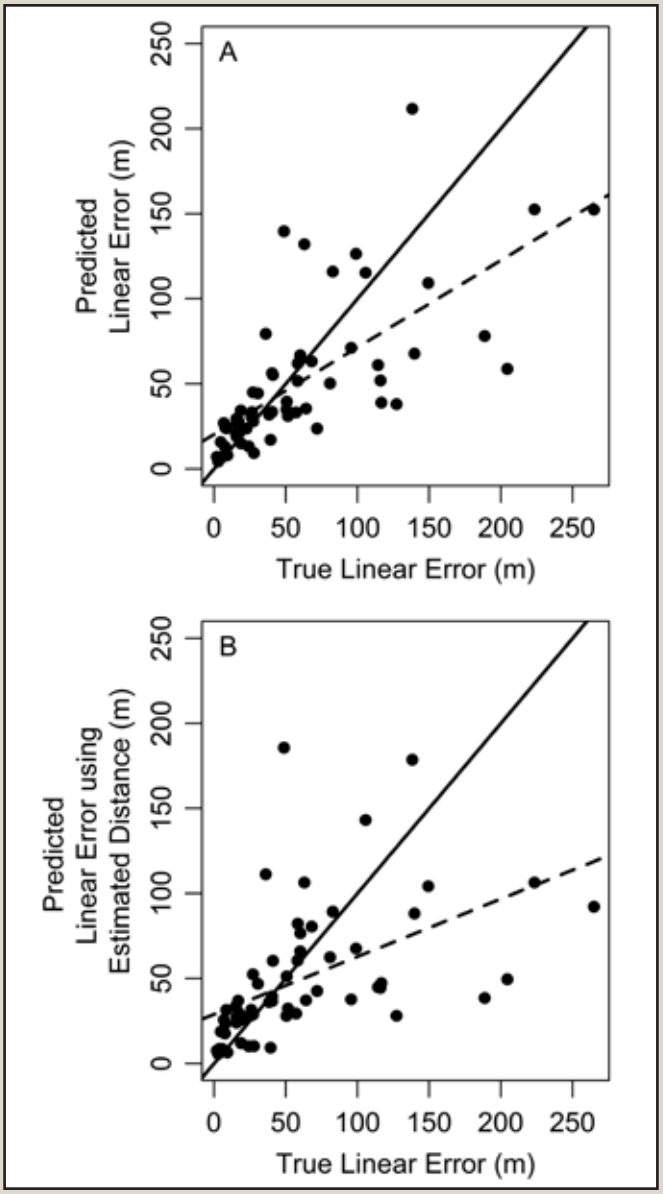

FIG. 2. Relationship between true linear error and predicted linear error using a model-averaged parameter estimates from a multiple regression analysis (2A) and a single-variable regression model containing only estimated distance (2B) from beacon tests (N = 60) of radio telemetered Eastern Indigo Snakes *(Drymarchon couperi)*. The solid line represents a one-to-one relationship between true and predicted linear error and the dashed line represents the observed relationship.

measuring the distance between the snake's actual location and the MLE or AE estimated location. We also assessed accuracy by calculating bias as the angle between the snake's actual location and each bearing (i.e., angular error) averaged across all bearings (N = 211, Withey et al. 2001). We also measured coverage as the proportion of actual snake locations that were contained by their respective MLE and AE error ellipses. To quantify precision, we used the size of the 95% confidence ellipse (ellipse area) and the standard deviation of the angles between the snake's actual location and each bearing across all bearings (angular precision).

Statistical analysis.—For each set of bearings (both beacon tests and triangulated locations), we measured the mean distance from the observer to the MLE or AE estimated location (estimated distance). We also measured the width of the angle between the two outermost bearings within each set (angle width). We characterized the dominant vegetation class (dominant vegetation) for each bearing set as forested (dominated by trees > 4 m tall and including citrus, bayheads, riparian forests, hammocks), shrub (primarily fire suppressed scrub and scrubby flatwoods with vegetation 2–4 m tall), and open (vegetation height < 2 m including scrub, scrubby flatwoods, pasture, and non-forested wetlands) using National Agriculture Imagery Program (NAIP) aerial imagery taken in Dec. 2011. We inspected the length of each bearing within a set using Google Earth and visually estimated the proportion of each vegetation class intersecting each bearing between the observer and the telemetered snake. We assigned each set of bearings to the vegetation class containing the greatest cumulative proportion across all bearings. However, the presence of dense vegetation along one bearing could potentially skew results even if other bearings are unobstructed. We therefore included a separate vegetation variable (thickest vegetation) where we assigned each set of bearings to the thickest vegetation class intersecting > 50% of any bearing in that set. We recorded the total time taken to complete each beacon test or triangulated

location for the 50 (94%) beacon tests and 80 (77%) triangulated locations for which we record time at each bearing. We also recorded the time from when the bearings were taken (measured as the median time between the first and last bearing) and when the snake was located. For beacon tests, we recorded whether or not the telemetered snake was in a location where it had been previously located to evaluate the influence of potential bias in triangulation caused by the snake repeatedly using the same retreat site. We also recorded each telemetered snake's position upon location following a beacon test (underground, on the surface but stationary, or on the surface and moving).

We used the beacon test data to evaluate the effects of estimated distance, angle width, ellipse area, number of bearings (3–5), observer (N = 3), position, previous location, and dominant and thickets vegetation class on linear error for AE and MLE locations. We hypothesized that angle width would have a quadratic rather than a linear effect (Haskell and Ballard 2007) so we only considered the quadratic effect of angle width. Estimated distance, ellipse area, and linear error were log transformed to correct for non-normality. Estimated distance and ellipse area were moderately correlated (Spearman's rank correlation, $r_s = 0.63$) but all other continuous variables had comparatively low colinearity ($|r_s| \leq 0.26$). Although we hypothesized that each of our predictor variables would influence linear error, we had no *a priori* reason to use any particular combination of these variables. Additionally, we were interested in understanding the independent contribution of each variable to the variation in linear error. We therefore fit linear regression models to all possible subsets of our variables. This allowed us to use hierarchical variance partitioning to estimate the independent contribution of each variable to the variance of the global model as a means of identifying the most causal factor (Chevan and Sutherland 1991; Mac Nally 2000). We used the hier.part package (v. 1.0-4, Walsh and Mac Nally 2013) to calculate the independent contributions of each variable. Because our ultimate goal was to predict linear error using data from the beacon tests, we used model-averaging (Burnham and Anderson 2002) across all our models with Akaike's Information Criteria adjusted for small sample sizes (AIC_c) in the MuMIn package (v. 1.10.0, Barton 2014) to obtain model-averaged parameters and 95% confidence intervals. We evaluated the predictive accuracy of our model by comparing the difference between true linear error and predicted linear error for the beacon test data. We then used these model-averaged parameters to predict linear error for the triangulated locations and recorded the number of triangulated locations with predicted accuracy ≤ 15 and 30 m. We selected these cutoffs because these were the pixel sizes of available land cover maps for our study area and thus represent possible minimum accuracies for resource selection analyses. All statistical analyses were conducted in R v. 3.0.2 (R Development Core Team 2013).

Results

We surgically implanted radio transmitters into 32 Eastern Indigo Snakes. Two individuals were lost < 30 days of release, presumably because of transmitter failure. We conducted 63 beacon tests using 19 telemetered snakes. The AE failed to produce estimates for three beacon tests despite the absence of potential outlying bearings so we excluded them from subsequent analyses to facilitate comparison between AE and MLE. Median distance from the observer to the beacon was 145 m (range: 21–606 m). Median angle width was 105° (range: 39–176°). Median time between the first and last bearings for each beacon test was 14 min (range: 5–41 min). The median time between taking the bearings and locating the telemetered snake was 29 min (range: 9–133 min). Excluding the maximum value of 133 min reduced the maximum to 67 min. Forty-one snakes (68%) were underground while 17 (28%) were moving on the surface and two (3%) were stationary on the surface. We used three bearings in 34 (57%) of our beacon tests, four bearings in 21 (35%), and five bearings in five (8%). We classified 38 (63%) bearings as having a dominant vegetation class of open, 16 (27%) as shrub, and 6 (10%) as forested. We classified 19 (32%) bearings as having a thickest vegetation class of open, 29 (48%) as shrub, and 12 (20%) as forested.

The AE and MLE produced similar estimates of accuracy and precision (Table 1). The maximum difference in linear error between each estimator was 3 m although the median difference between the two estimators was marginally significant ($V = 684$, $P = 0.0897$). Mean bias was 1.41° (median = 2.53°) and angular precision was 16.50°. However, a single bearing had an extremely large angular error (102°). Excluding this value changed the mean bias to 1.97° (median = 2.54°) and angular precision to 14.92°. Coverage was low as only seven (12%) and eight (13%) (MLE and AE, respectively) confidence ellipses included the true location. Median ellipse size was greater for AE than MLE (Table 1) but this difference was not statistically significant ($V = 852$, $P = 0.6454$).

Because of the moderate correlation between estimated distance and ellipse area we repeated our beacon test analyses excluding ellipse area from our pool of predictor variables. Our results were similar so we report the results using all predictor variables. Results were also similar between MLE and AE so we report the results of the former because of its lower failure rate. Distance to estimated location was present in all the best supported models ($AIC_c < 2$; Table 2) and explained almost half of the variance in linear error (Fig. 1). Linear error increased with increasing distance from estimated location (Table 3). All other predictor variables explained comparatively little variation in linear error and only the number of bearings, dominant vegetation class, and observer had model-averaged 95% CI that did not overlap zero (Fig. 1). Linear error was greatest when three bearings were used and mean linear error decreased by 42% and 50% when four and five bearings where used, respectively (Table 3). Mean linear error varied by up to 48% among the three observers. Mean linear error decreased by 59% and 47% when the dominant vegetation class traversed by all bearings within a set was shrub and open, respectively, instead of forest.

The median difference between true and predicted linear error for the beacon tests was -1.13 m (range: -91–146 m) and was not significantly different from zero ($V = 1035$, $P = 0.3790$). The median difference between true and predicted linear error for the beacon tests predicted using only estimated distance was -2.34 m (range: -138–173) and was not significantly different from zero ($V = 1001$, $P = 0.5291$). Although the differences between true linear error and predicted linear error using the model-averaged parameter estimates and estimated distance were not significantly different ($V = 948$, $P = 0.8109$), our predictions of linear error were improved by using the model-averaged parameter estimates (Fig. 2). Eleven (18%) and twelve (20%) beacon tests had true linear error ≤ 15 m with MLE and AE, respectively. Nine (15%) and 10 (17%) beacon tests had predicted error ≤ 15 m with MLE and AE, respectively. Twenty-four (40%)

TABLE 2. Top multiple regression models predicting linear error between true locations and triangulated locations estimated using maximum likelihood from Eastern Indigo Snake (*Drymarchon couperi*) beacon tests (N = 60). For each model we report Akaike's Information Criteria corrected for small sample sizes (AIC_c), delta AIC_c (AIC_c), the AIC_c model weight (w_i), and the adjusted R^2. Only models with $AIC_c < 2$ are reported; a total of 381 models were considered. Angle width includes a quadratic effect.

Model	AIC_c	AIC_c	w_i	R^2
Distance + ellipse area + angle width + no. of bearings + observer	138.28	0.00	0.067	0.63
Distance + angle width + no. of bearings + observer	138.93	0.66	0.049	0.62
Distance + no. of bearings + observer	139.25	0.97	0.041	0.60
Distance + angle width + dominant vegetation + duplicate location	139.43	1.15	0.038	0.61
Distance + angle width + dominant vegetation	139.48	1.20	0.037	0.60
Distance + no. of bearings + duplicate location	139.54	1.26	0.036	0.59
Distance + ellipse area + no. of bearings + observer	139.55	1.28	0.036	0.60
Distance + angle width + no. of bearings + observer + duplicate location	139.62	1.35	0.034	0.62
Distance + no. of bearings + thickest vegetation + duplicate location	139.65	1.38	0.034	0.60
Distance + angle width + no. of bearings + dominant vegetation + duplicate location	139.67	1.39	0.034	0.62
Distance + ellipse area + angle width + dominant vegetation	140.08	1.80	0.027	0.60
Distance + no. of bearings + dominant vegetation + duplicate location	140.12	1.84	0.027	0.60

and 22 (37%) beacon tests had true and predicted linear error, respectively, ≤ 30 m for both estimators.

We collected 116 triangulated locations from 16 telemetered snakes. The AE failed to produce estimates for nine beacon tests so we excluded them from subsequent analyses to facilitate comparison between AE and MLE. Distance from observer to estimated location ranged from 20–737 m and 20–743 m for AE and MLE, respectively (Table 1). Median time between first and last bearing was 15 min (range: 3–85 min) and median angle width was 94° (range: 22–178°). We used three bearings for 44 (41%) triangulated locations, four bearings for 52 (49%), and five bearings for 11 (10%) of our triangulated locations. We classified 78 (73%) bearings as having a dominant vegetation class of open, 11 (10%) as shrub, and 18 (17%) as forested. We classified 40 (37%) bearings as having a thickest vegetation class of open, 27 (25%) as shrub, and 40 (37%) as forested. Median ellipse size estimated with AE was significantly greater than median ellipse size estimated using MLE ($V = 1{,}642$, $P = 0.0001$, Table 1).

We used all variables from the beacon test analysis for predicting linear error for our triangulated locations except the snake's position and whether or not it was at a previously used retreat site because these variables were unknown for triangulated locations. Median predicted linear error for the triangulated locations was very similar between AE and MLE (Table 1). Median difference in predicated linear error between the two estimators was significantly different from zero ($V = 4699$, $P < 0.0001$) but the magnitude of this difference was very small (median = 0.28, 25th percentile: 0.04, 75th percentile: 1.21). Predicted linear error was ≤ 15 m for 25 (23%) triangulated locations and ≤ 30 m for 40 (37%) triangulated locations for both estimators.

DISCUSSION

Our results show that distance to estimated location had the strongest effect on linear error, consistent with other triangulation studies (Marzluff et al. 1997; Bartolommei et al. 2012). Additionally, the predictive ability of our multiple regression models was poorest at large distances as indicated by the large residual errors shown in Fig. 2. Angular error is magnified with increasing distance from the transmitter and other factors, such as poor signal quality, may have a greater effect over long distances (Hupp and Ratti 1983; Saltz and Alkon 1985). Reducing distance between the observer and telemetered animal is often used to reduce triangulation error in studies not reporting the use of beacon tests (e.g., Dickson et al. 2005). However, other studies have not reported a strong effect of distance to estimated location on accuracy (Hupp and Ratti 1983; Haskell and Ballard 2007) suggesting that, while reducing estimated distance may reduce triangulation error, it may not guarantee sufficient accuracy for a study's objectives. The size of the 95% confidence ellipse explained the second greatest amount of variation in linear error although the model-averaged 95% confidence intervals overlapped zero. However, these ellipses rarely contained the true location during beacon tests. This result is consistent with previous studies (Nams and Boutin 1991; Withey et al. 2001) and reinforces caution in using the 95% confidence ellipse to infer accuracy. We found relatively little support for angle width although Haskell and Ballard (2007) found a strong quadratic effect of angle width and recommended an angle width of 90–100° to maximize accuracy.

Features common to many radio telemetry studies on herpetofauna likely influenced our triangulation accuracy. In particular, the low vertical height of our transmitters (at or below ground level) may have reduced our accuracy. Townsend et al. (2007) found approximately a four-fold increase in angular error (6.43° to 24.37°) when reducing a transmitter's height from 92 cm to 15 cm above ground-level. Many snakes and other herpetofauna also spend large amounts of time underground or in thick vegetation which could similarly reduce triangulation accuracy (Lee et al. 1985; White and Garrott 1990). Beacon tests taken where bearings primarily passed through shrub vegetation were less accurate than those in forested vegetation. This result could be due to the dense vegetation structure of the habitats we classified as shrub. Snake position had very little influence on linear error despite the fact that most individuals located on the surface during beacon tests were moving (17 of 60 beacon tests). This suggests that any movement between when the bearings were taken and when the snake was located was small relative to the degree of error in our triangulations.

TABLE 3. Model-averaged parameter estimates, standard errors, and 95% confidence intervals from a multiple regression analysis of Eastern Indigo Snakes (*Drymarchon couperi*) radio telemetry beacon tests (N = 60). Log of distance between true location and triangulated location estimated using Lenth's maximum likelihood estimator (MLE) was used as the response variable. The reference levels for number of bearings, observer, dominant and thickest vegetation, and position were five bearings, observer #3, forested, and moving, respectively.

	Estimate	SE	Lower CI	Upper CI
Intercept	0.0130	1.4981	-2.9233	2.9493

Position (underground)	-0.0700	0.2542	-0.5682	0.4282

Including these locations improves the applicability of our predictive model, even at the risk of under-predicting accuracy, because such small-scale movements or even whether an animal is underground or on the surface are undetectable during triangulation. Nevertheless, animal movement while bearings are taken can reduce triangulation accuracy (Schmutz and White 1990) and many studies employ multiple observers (Marzluff et al. 1997) or limit the time between bearings (Cimino and Lovari 2003; Dickson et al. 2005) to minimize this error. A post-hoc analysis showed that the median time between the first and final bearing to when the snake was located (i.e., time to location) was positively correlated with linear error ($r_s = 0.67$, $P < 0.0001$) suggesting that accuracy was improved by locating the snake soon after the bearings were taken. However, time to location was also correlated with estimated distance ($r_s = 0.63$, $P < 0.0001$) and these patterns held true when considering underground snakes as well as those moving on the surface. This suggests that the relationship between linear error and time to location may have been an artifact of the observer taking longer to locate snakes that were further away from where the bearings were taken. Additionally, there was no significant difference in time to location between snakes underground or on the surface ($W = 304$, $P = 0.3884$).

We observed very little difference in precision or accuracy between MLE and AE, consistent with other studies (Haskell and Ballard 2007; Withey et al. 2001). However, AE failed to converge in some instances. When reflected signals are common, AE appears to outperform MLE, although both estimators perform similarly in the absence of signal reflection (Garrott et al. 1986; White and Garrott 1990). We observed relatively little signal reflection in our study area although we occasionally had difficulty determining the signal's bearing or recorded bearings that did not intersect the other bearings in a set. This may have been caused by thick or damp vegetation or other unknown factors. These bearings would likely have been removed as outliers so this may have contributed to the similarity of our results. Previous studies comparing MLE and AE do not report the treatment of outliers or included them to test the method's sensitivity. However, outlying bearings were present in only 10 of our 60 beacon tests and 15 of our 107 triangulated locations. In four beacon tests removing the outlier allowed both estimators to converge and removing outlying bearings in another three beacon tests reduced linear error by 4, 37, and 56 m. However, removing outliers increased linear error increased in the remaining three beacon tests by 1, 9, and 91 m. While defining outliers involves subjectivity at some level, erroneous bearings may ultimately become detrimental to the goal of accurately estimating triangulated locations (Garrott et al. 1986).

Less than 40% of our triangulated locations met our criteria for suitable accuracy. The criteria for suitable accuracy will depend on the study objectives, composition of the landscape, and degree of error relative to the study organism's movement. For example, Moser and Garton (2007) found that fixed kernel home range size was relatively robust to triangulation error provided the degree of error is small relative to home range size. They used the median Circular Error Probable (CEP, Moen et al. 1997), the area of a circle with a radius that contains 50% of estimated locations, as a measure of error and found that a ratio of CEP to home range size < 0.01 had relatively little effect on fixed kernel home range estimates. Using our median observed linear error (41 m) to calculate CEP and a mean home range size of 140 ha (J. Bauder, unpubl. data), our error ratio was 0.004. Based on our median observed linear error, home range size would need to be > 53 ha to maintain an error ratio < 0.01. While Eastern Indigo Snake home range sizes regularly exceed this size (Breininger et al. 2011; Hyslop et al. 2014), many snake species maintain smaller home ranges (Bauder et al., *in press*; Row and Blouin-Demers 2006) suggesting that the degree of triangulation error observed in our study may be too great to produce reliable home range estimates for many snake species. These errors may also be compounded in linear or irregularly shaped home ranges. Resource selection analyses can also be sensitive to triangulation error. Montgomery et al. (2011) found that triangulation errors are compounded with fine-resolution (e.g., 10 m vs. 30 m pixels) categorical raster data and small patch sizes. Using their simulation results and our median observed linear error (41 m), accuracy of habitat classification at patch sizes from 0.5–50 ha would range from 52–81% and 62–84% at 10 m and 30 m pixels, respectively. Many snakes use small-scale or linear habitat features (Blouin-Demers and Weatherhead 2001; Pattishall and Cundall 2008) and triangulated locations may require a higher degree of accuracy than we obtained in order to detect use of such features.

Our results suggest that the error associated with triangulation may be insufficient for snake radio telemetry studies. We recommend that researchers avoid triangulation in snake radio telemetry studies and use beacon tests to directly

measure linear error when triangulation is used. Researchers should use data from beacon tests to predict the linear error of triangulated locations to determine which locations are sufficiently accurate given the study's objectives. Our study also offers suggestions for minimizing linear error. The observer should minimize the distance between themselves and the transmitter. Bearings should be taken within the shortest amount of time or simultaneously with multiple observers to minimize the potential for animal movement. The same observers should be used throughout the study because inter-observer variability may be high. Finally, we recommend that observers plot their bearings while in the field using field maps or computers. This will allow them to identify potentially erroneous bearings and reestimate a location while still in the field instead of discarding outlying bearings.

Acknowledgments.—We thank Linda LaClaire and the U.S. Fish and Wildlife Service for providing the funding for this project through a Cooperative Agreement under the Endangered Species Conservation – Recovery Implementation Fund, and Christopher Jenkins and The Orianne Society for providing support to JB. Zach Forsburg and Lance Paden collected the radio telemetry data. The Archbold Biological Station allowed us use of their housing and laboratory facilities and Betsie Rothermel provided valuable logistical support. We thank the many scientists, interns, and volunteers at the Archbold Biological Station for helping to search for and report observations of Eastern Indigo Snakes. Nicole Ranalli and Brad Kolhoff coordinated access to the Florida Fish and Wildlife Conservation Commission properties. We thank the many private landowners that allowed us to search for and radio track Eastern Indigo Snakes on their property. Heidi Hall, Karen McClain, Sue Bottoms, Patty Li, and Jerry Medlock assisted with various administrative aspects of this project. The comments of Daniel Saenz and two anonymous reviewers greatly improved this manuscript. All study procedures were approved under an Institutional Animal Care and Use Committee (IACUC) protocol for the Archbold Biological Station (#ABS-AUP-002-R) and the University of Florida (#200903450) and a Federal Fish and Wildlife Permit from the U.S. Fish and Wildlife Service (#TE28025A-1).

New Wine in Old Bottles: Using Modified Hoopnets to Catch Bait-Averse Basking Turtles

One of the most popular trap designs for capturing freshwater turtles for research is the baited three-hoop trap, which has a funnel-shaped throat of netting on the front hoop designed to facilitate ingress and block egress (Lagler 1943; Legler 1960; Vogt 2012). Oftentimes, however, certain target species are poorly sampled in baited traps (e.g., *Graptemys* spp., *Pseudemys* spp., *Sternotherus* spp.; Lagler 1943; Cagle and Chaney 1950; Plummer 1979; Browne and Hecnar 2005; Sterrett et al. 2010; Vogt 2012). Many of the bait-averse species are habitual baskers, thus a variety of basking trap designs have been described for catching such species. Many basking traps described in the literature work by inducing turtles to bask on platforms that are a component of the trap and some designs have additional components to prohibit turtles from climbing out of the traps after capture; such traps tend to be relatively cumbersome (e.g., Lagler 1943; Cagle 1950; Ream and Ream 1966; MacCulloch and Gordon 1978; Plummer 1979; Browne and Hecnar 2005; Valdeón et al. 2010) and are difficult to use in lotic habitats. As an alternative, open-top basking traps constructed of netting or PVC-coated crawfish wire have been placed at or just below the water's surface underneath natural basking substrates in lotic habitats; basking turtles are startled into the traps and then removed before they climb or swim out (Plummer 1979; Jones and Hartfield 1995; Horne et al. 2003; Jones 2006; Selman et al. 2012; Vogt 2012).

I describe a modification of the standard three-hoop turtle net that makes an efficient and easily transportable open-top basking trap for basking, bait-averse turtles. I have used the design to catch turtles on four Gulf Coastal river systems and detail some of my experiences with this new trap design, including captures per trap-day and, for one season on one river, captures per turtle observed basking over a trap.

I trapped turtles in the Alabama River in Autauga and Lowndes counties, Alabama, in early July 2011 and mid June 2012 and 2013 and at a variety of sites on the Mermentau, lower Calcasieu, and Sabine river drainages in southwestern Louisiana, including the border with Texas, in May and early June 2012 and 2013. Trapping time on the Alabama was limited to ca. 4–5 hours most days due to water releases from an upstream dam that raised the river level daily by more than 1 m; times spent on the Mermentau, Calcasieu, and Sabine drainages were more variable, but rarely allowed more than 3–5 boat passes per basking trap.

To modify hoopnets as basking traps, I cut the netting at the front of the middle hoop of five 0.9-m diameter hoopnets (2.5-cm mesh) such that the front part of each original trap consisted of a hoop, outside netting to the point cut, and throat, while the back part consisted of two hoops and netting gathered at the back. The throat of each front section was then cut away from the first hoop, sewn to that hoop's outside netting, and tied shut, yielding 10 open-top nets from the original five traps (Fig. 1). In setting the nets as basking traps underneath logs and branches used by basking turtles, I rotated them 90º so that their open ends faced upward and tied them in place with two nylon ropes or pieces of twine so that the opening was approximately flush with the water's surface (Fig. 2). A weight in the bottom of each net

FIG. 1. Two basking traps constructed from a single hoopnet, by removing the two back hoops (left) and cutting the throat out of the inside of the former first hoop and sewing it to its outside netting, such that the former throat is now the bottom of the net (right).

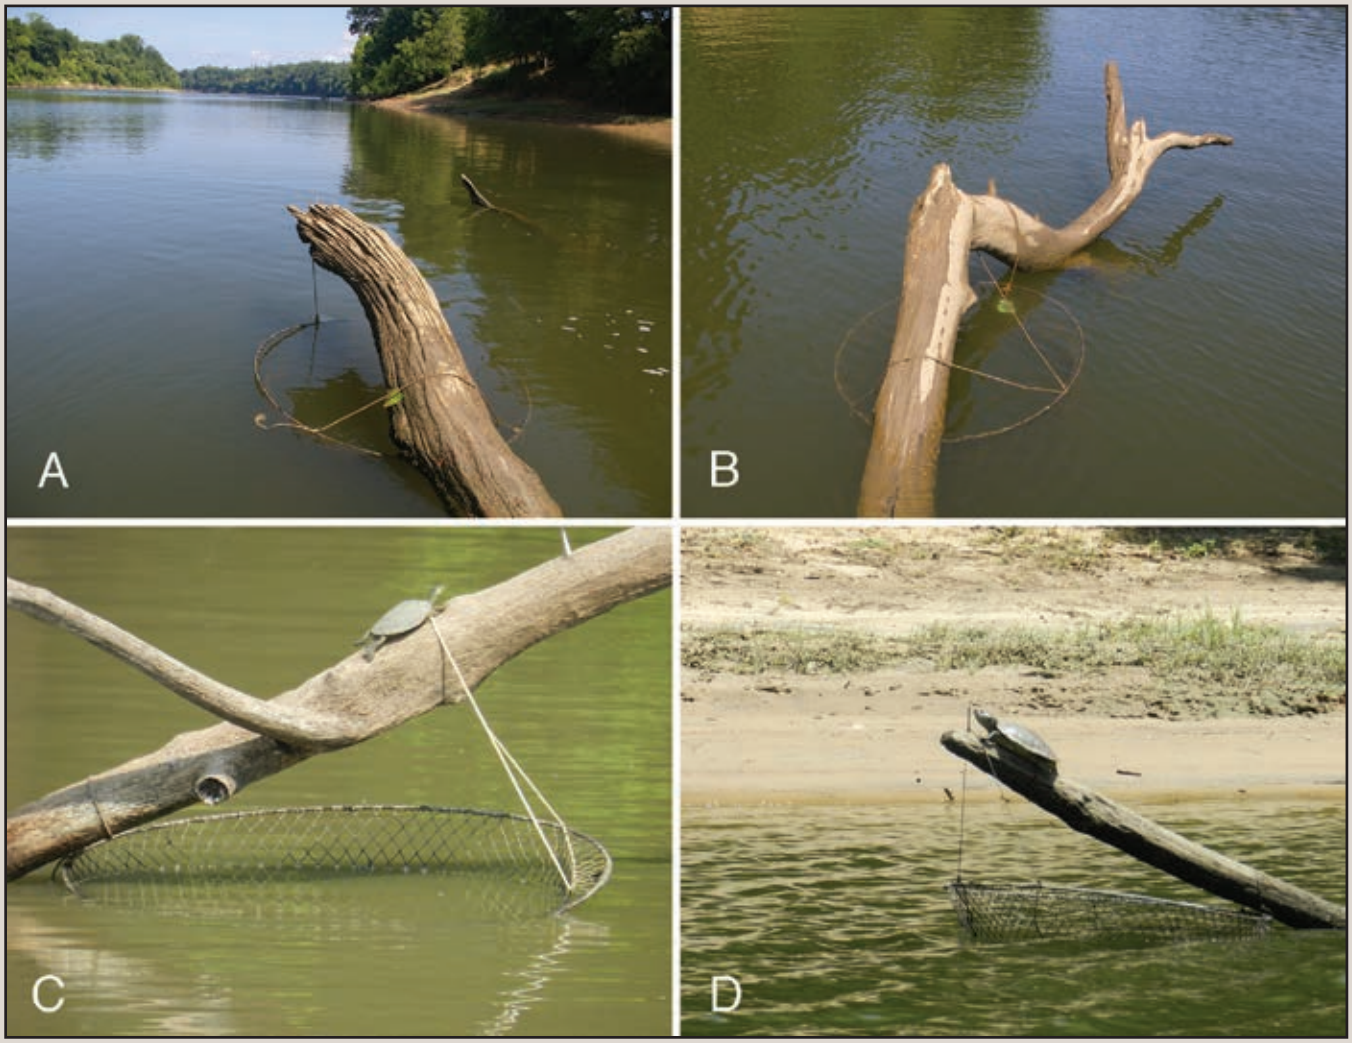

FIG. 2. High-yield basking traps set under (A) a large, angled log and (B) an archway site on the Alabama River and map turtles basking over traps moments before capture: (C) *Graptemys sabinensis*, Bayou Plaquemine Brule on the Mermentau drainage, male, midline PL 90 mm; (D) *Graptemys pulchra*, Alabama River on the Mobile Bay drainages, female, midline PL 188 mm.

extended its depth to ca. 1–1.5 m (deeper for the double-hooped rear sections of the original traps), so that turtles diving into the traps could dive deeply into the nets before encountering confinement. Additional traps deployed were 0.91-m diameter hoopnets baited with canned tuna in Louisiana and unbaited 0.91-m diameter fykenets with 5-m lead nets (Vogt 2012) in Alabama and Louisiana.

Turtles were spotted over traps with the aid of binoculars and approached rapidly in a jonboat, eliciting a flight response (Selman et al. 2012). Due to shallow water that did not allow use of an outboard motor, a canoe and paddles were used in one four-day trapping session on a tributary of the Calcasieu, the Whiskey Chitto River, and another three-day trapping session on the Sabine. During 2012 trapping on the Alabama River, I recorded hours spent on the river, numbers of turtles that I attempted to induce to jump into nets, and numbers captured. I measured the midline plastron length (PL) of turtles I captured, marked them (Cagle 1939), and released them at their sites of capture.

Using hoopnet basking traps on the Alabama River, I captured 82 turtles in 80 trap-days in 2011, 67 turtles in 73 trap-days in 2012, and 59 turtles in 49 trap-days in 2013, for an overall average of 1.03 turtles/trap-day. Pooling years, I captured 125 *Graptemys nigrinoda*, 61 *Graptemys pulchra*, 13 *Pseudemys concinna*, and 9 *Trachemys scripta* on the Alabama. Using hoopnet basking traps on the Mermentau, Calcasieu, and Sabine rivers, I captured 79 turtles in 119 trap-days in 2012 and 92 turtles in 140 trap-days in 2013, an overall average of 0.66 turtles/trap-day, including 141 *Graptemys sabinensis*, 17 *Graptemys pseudogeographica*, 10 *P. concinna*, and 3 *T. scripta*. While some traps caught no turtles on one or more days, at the other extreme, some caught as many as 10 turtles per day. Among the highest-yielding traps, with frequent multiple captures (i.e., more than one turtle at a visit), were those situated under "archway" sites, i.e., deadwood that projected out of the water and then back down into the water, allowing turtles to access the site from either end (e.g., Fig. 2b).

Capture success was for the most part lower for baited hoopnets and unbaited fykenets. In Louisiana, I captured 0.20 turtles/hoopnet-night (21 turtles in 103 trap-nights) and 0.85 turtles/fykenet-night (121 turtles in 143 trap-nights). In Alabama, I captured 0.33 turtles/fykenet-night (50 turtles in 150 trap-nights).

On the Alabama River in 2012, hoopnet basking traps captured 56% of turtles judged to be situated above their openings (67 of 119) and the overall rate of capture was 2.52 turtles/10 trap

TABLE 1. Capture success of basking traps on the Alabama River in 2012, with success rate (percent of turtles observed over traps that were captured) and number of captures per 10 trap-hours (10 being the typical number of traps deployed at one time).

Date	Captures	Misses	Success rate (%)	Trap hours	Captures/ 10 trap hours
11 June 2012	2	2	50	21	0.95
12 June 2012	19	5	79	34	5.59
13 June 2012*	2	6	25	24	0.83
14 June 2012*	2	3	40	16	1.25
15 June 2012*	10	17	37	40.5	2.47
16 June 2012	16	7	70	53	3.02
17 June 2012	7	7	50	43.5	1.61
18 June 2012	9	5	64	33.5	2.69
Total	67	52	56	266	2.52

*Dates when the river was higher and more variable than at normal pool levels.

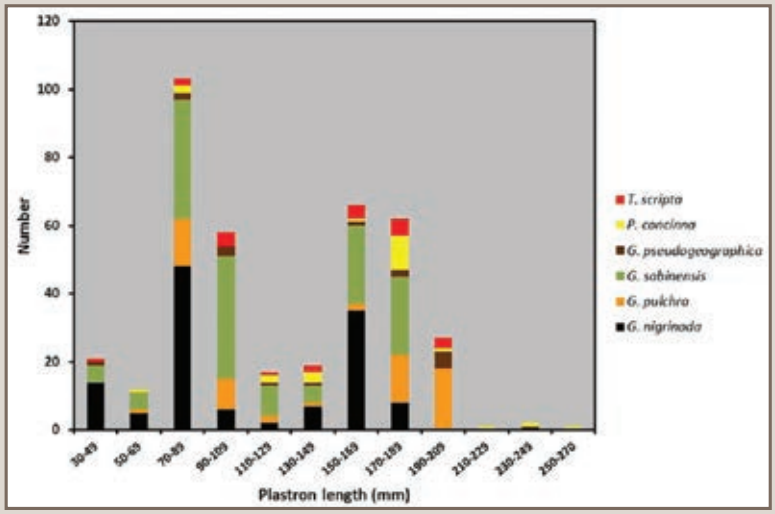

FIG. 3. Length-frequency distribution of six turtle species captured in hoopnet basking traps in the Alabama, Mermentau, Calcasieu, and Sabine river drainages, 2011–2013.

hours, or a turtle every 4.0 hours a trap was in place (Table 1). Most of the 52 misses were probably a result of turtles jumping beyond the trap rims, as I observed no turtles scrambling out over the tops of nets during my approach. Trap success varied considerably by day in total numbers of turtles captured, percentage of turtles over traps captured, and hourly capture rates (Table 1). I believe variability in success was largely a result of unpredictable river levels, because trapping in 2012 followed two days of moderately heavy rain that resulted in variable and less predictable dam releases for three days (13–15 June), which made it difficult to keep traps at optimal heights. Trap success rate and capture rate were low on these three days, with capture rate being significantly lower than it was the other five days in a 2 × 2 Chi-square contingency test (35% for 13–15 June vs. 67% for other days, Table 1; $\chi^2 = 11.11$, $p = 0.0009$). Trap success may thus be partially compromised by river conditions that are influenced by recent precipitation events. The trap described thus has the disadvantage of not adjusting with fluctuating water level, as various designs of floating basking traps do (Plummer 1979), however, floating platform traps do not work well in even moderate river currents (pers. observ.) or in lotic habitats with abundant existing basking substrates (W. Selman, pers. comm.). Hoopnet basking traps should thus be tied to basking substrates in a manner that allows easy and rapid adjustment of their height in the water column.

Turtles were almost always at the bottoms of nets when I reached them. Some care is necessary in pulling up the inside of the nets to retrieve turtles, as two of the "misses" in Table 1 came from trapper error, i.e., allowing turtles to escape over the top hoop as the traps were pulled upward.

The size-frequency distribution of turtles captured in basking traps shows that all size classes were well represented among captures, from a hatchling *G. sabinensis* measuring 36 mm PL to a female *P. concinna* measuring 265 mm PL (Fig. 3). The highly bimodal nature of the distribution is a consequence of the dominance of species of *Graptemys*, which are strongly sexually size dimorphic (Lindeman 2013). The size classes ≥ 210 mm in PL were only lightly populated (3 female *P. concinna* and 1 female *G. pseudogeographica*), because the only species that commonly reaches this size, *P. concinna*, was substantially less common in the basking turtle fauna than the smaller *Graptemys* spp. and *T. scripta*. The traps should capture large *Pseudemys* spp. well in habitats where they are more abundant, although a larger hoop diameter may better target larger turtles.

Paddling a canoe toward traps worked moderately well on the upper Sabine River, where capture rate was 0.4 turtles/trap-day (11 turtles in 27 trap-days), but yielded no captures in 8 trap-days on the Whiskey Chitto River. The difference was likely related to basking frequency, which was markedly lower on the Whiskey Chitto than on the Sabine during trapping days. Checking traps from a canoe meant less of the river could be covered and fewer checks of traps were possible, thus a motorized boat remains the better option in river reaches that are deep enough.

It was not uncommon to recover turtles not seen over traps before approach, demonstrating the ability of traps to occasionally hold turtles for long periods of time. These bonus or "Easter-egg" turtles were captured both when trap rims were slightly above the surface or slightly below and were always at the bottom of the trap when it was pulled up, suggesting that the ca. 1- to 1.5-m depth of the traps may be an added advantage of the design. In my experience, turtles often rapidly escape basking frame traps (the design of MacCulloch and Gordon 1978) with shallower nets (ca. 30–50 cm) and trapping turtles that were not seen on the basking platform of the trap during approach is much rarer.

All nets in the present study were set under logs and branches that projected up from the water at an angle (Fig. 2), so that traps could be set with the opening flush with or just above the river surface in an attempt to limit escapes. In a habitat in which the main basking substrates lie flat at the surface with a substantial underwater portion, as with floating logs, modification will be necessary to avoid setting the opening too low in the water column. Nails and twine can be used to secure a trap alongside a horizontal log, with additional nails on the opposite side of the

log to prevent turtles from escaping into the water on that side, as described by Selman et al. (2012).

Two advantages of the method described over many other basking trap designs are ease of transport and cost. Ten traps collapse to a 1-m circle that stands ca. 15 cm high and thus take up little space in a trailered boat or in the back of a vehicle, in contrast to the bulky three-dimensional shape of crawfish-wire traps and traps with treadles. A 4.3-m jonboat can hold 15–18 nested crawfish-wire traps of various sizes, but they take up the majority of the deck and hull space (W. Selman, pers. comm.). Cost of five hoopnets that can be modified to produce 10 basking traps is ca. US $600 plus shipping (Memphis Net and Twine, Memphis, Tennessee).

Acknowledgments.—I thank W. Selman, who demonstrated the use of jonboat approach with crawfish-wire traps on the Alabama River for me in 2009 and thus helped to motivate the conception of my new trap design. Trapping was ably assisted by A. Fehrenbach and S. McFadden in Louisiana in 2012 and F. Armagost in Louisiana and Alabama in 2013. The manuscript was improved by the comments of J. Godwin and W. Selman. Trapping was carried out under Scientific Collecting Permits issued by the states of Alabama (2011000059266860, 20120000086566860, and 20130000058066860), Louisiana (LNHP-11-076, LNHP-12-070, and LNHP-13-026), and Texas (SPR-0513-059). Field work was funded by a Faculty Professional Development grant from the Pennsylvania State System of Higher Education and a Louisiana State Wildlife Grant.

Detection of Ranavirus in Northeast Ohio's Wetlands

Given the role of pathogens, such as *Ranavirus* spp., in amphibian die-offs and declines (Dazak et al. 2003; Stuart et al. 2004) it is important to document their distribution and prevalence. Ranavirus was only recently reported in Ohio, from *Ambystoma maculatum* (Spotted Salamander), *Lithobates catesbeianus* (American Bull Frog), *L. clamitans* (Green Frog), *L. sylvaticus* (Wood Frog), and *Anaxyrus americanus* (American Toad) at Taylor-Ochs Pond in Granville (Homan et al. 2013). Here we document ranavirus in a new geographic location in northern Ohio and add *L. palustris* (Pickerel Frog) as new species to the list of amphibians with ranavirus infection in Ohio (Miller et al. 2011).

While conducting a Cleveland Metroparks district-wide vernal pool inventory on 4 June 2010 an amphibian mortality was observed within Mill Stream Run Reservation. The event involved several hundred amphibian larvae at three separate wetlands less than 200 m apart. Across all three sites we observed a total of approximately 200–300 morbid larval *Lithobates sylvaticus* that appeared emaciated and had sloughing skin, ~15 *Pseudacris crucifer* (Northern Spring Peeper) with red and swollen hind legs, and ~ 5 *Ambystoma* spp. (mole salamander) with no obvious signs of disease. The live *L. sylvaticus* larvae appeared emaciated, with sloughing skin and had difficulty swimming and were near the surface. Five recently dead *L. sylvaticus* larvae were collected and preserved in 70% ethanol. The observation of this mortality event initiated the planning and implementation of additional surveillance of amphibian mortality events and determining the cause.

From April–June 2011 weekly site visits were conducted at three pools in Mill Stream Run Reservation (specimens were collected in only two of the three pools, MSR #1 & 2), three pools in North Chagrin Reservation (NCR #1–3), and three pools in South Chagrin Reservation (ultimately only one had amphibians, SCR) all within Cleveland Metroparks. Surveillance and monitoring continued the following year from April–June, 2012, excluding South Chagrin Reservation due to the low number of amphibians present; however, we added Sanctuary Marsh (SM) a wetland located in North Chagrin Reservation. During each site visit a visual survey of the entire wetland's perimeter was conducted without entering the water during which we searched for apparently ill amphibian larvae (e.g., emaciation or patchy pale coloration) or morbid tadpoles, and those with unusual behavior (swimming slowly near the surface or unable remain upright). Such animals were collected with a dip net and euthanized using Tricaine methanesulfonate (MS-222) and preserved in 70–95% ethanol. In addition, apparently healthy *L. catesbeianus* and *L. clamitans* larvae at SM and NCR#1, respectively, were collected in 2012. In all cases, equipment and boots were decontaminated with a 5% bleach solution between sites and dip nets were only used once per site to protect against cross contamination of samples and spread of the virus to non-infected pools.

The larvae collected in 2010 and 2011 were sent to the Amphibian Disease Laboratory at the San Diego Zoo Institute for Conservation Research to be screened for ranavirus. DNA was extracted from liver and kidney and pooled together in 2010 and the whole body in 2011 with DNAeasy Blood and Tissue kits (Qiagen Inc, Valencia, CA). The laboratory utilized the Taqman qPCR assay described by Pallister et al. (2007) that targets a small

Total				26/32	

section of the major capsid protein (MCP) gene of ranaviruses. The one modification was that the reaction was run for 55 instead of 40 cycles. Each sample was run in four wells: three to detect ranavirus and one well to detect possible PCR inhibition using a Taqman exogenous internal positive control (IPC; Applied Biosystems). A sample was considered positive when the Ct value was <50 in all three wells. If the Ct value was ≥ 50 the sample was considered negative. If 1 or 2 wells had Ct values < 50 the sample was run again using 5 wells (including one well for the IPC) and scored as positive if ≥ 3 wells had Ct values <50 and negative otherwise.

Samples collected in 2012 were analyzed at Baldwin Wallace University in Berea, Ohio. These samples were analyzed with standard PCR for the major capsid protein (MCP) gene of ranavirus using the primers MCP 4 & 5 and reaction conditions as described in Mao et al. (1997). Samples were scored positive for ranavirus if isolates possessed a prominent band at about 500 bp.

We found a total of 26 of the 32 amphibians tested were positive for the presence of ranavirus DNA (Table 1). This includes 13 of 18 *Lithobates sylvaticus*, 6 of 6 *L. clamitans*, 6 of 7 *L. catesbeianus,* and 1 of 1 *L. palustris* from two networks of ponds located 40.0 km apart (Fig. 1). Note, however, that these animals were selected because of their signs of illness and so these numbers do not reflect the actual prevalence of infection in the population as a whole. While it is unclear if the mortality event observed in 2010 was a direct result of a ranavirus infection, we found ranavirus DNA in all three recently dead *L. sylvaticus* and observed obvious hemorrhaging and edema, which is consistent with, but not diagnostic of, clinical signs of advanced ranavirus infection in amphibians (Miller et al. 2011). In 2011 *L. sylvaticus* at MSR#1 again appeared lethargic, swimming near the surface with pale patchy skin and with a small number of morbid animals observed. Interestingly the *L. catesbeianus* and *L. clamitans* larvae collected at SM in 2012 did not exhibit any gross signs of infection and there was no observable mortality, but these larvae tested positive for ranavirus DNA.

To our knowledge this is the first report of a ranavirus in northern Ohio. While ranavirus has been documented in *L. sylvaticus, L. clamitans,* and *L. catesbeianus* in Ohio, this is the first report of *L. palustris* in Ohio testing positive for ranavirus. We also documented the recurrence of ranavirus over two years in one wetland. This is important as it is believed that long-term presence and exposure within a population can potentially lead to local extirpation (Miller et al. 2011).

Acknowledgments.—We thank Cleveland Metroparks for providing funding for this project and Tyler Lawson and Karen Munroe from Baldwin Wallace University for the utilization of BWU's laboratory. Tom Kraft for producing the map and the numerous staff, students, and volunteers that assisted in monitoring pools and collecting specimens are greatly appreciated.

Multi-year Surveillance for *Batrachochytrium dendrobatidis* in Amphibians of Peninsular Malaysia

Chytridiomycosis, caused by the fungal pathogen *Batrachochytrium dendrobatidis* (*Bd*), is a threat to amphibian biodiversity and is causing amphibian population declines in many areas throughout the world (Lötters et al. 2009). Since its identification, this pathogen has been found on every continent where amphibians are present and is continuing to be found in many new countries (Fisher et al. 2009; Olson et al. 2013). Until very recently there have been relatively few surveys for the presence of *Bd* in Asia despite the incredible biodiversity of amphibians in that region. Recent surveys in the Peoples Republic of China have shown that *Bd* occurs with a prevalence of between 7.6% and 15% depending on the region sampled (Bai et al. 2010; Bai et al. 2012). In Japan there is an average prevalence of 27% (Goka et al. 2009) whereas South Korea has been reported to have an average prevalence of 38% (Yang et al. 2009). There also have been sporadic reports of *Bd* incidence in Indonesia (Kusrini et al. 2008). A recent survey of amphibians in Thailand, close to the Malaysia border, found one positive *Bd* sample out of six samples (Vörös et al. 2012).

Peninsular Malaysia has a high level of amphibian biodiversity with many new species still being discovered. The first published survey of *Bd* in Peninsular Malaysia completed in March 2010 detected *Bd* in 10 out of 127 individuals sampled for an overall prevalence of 7.8% (95% confidence interval, 4–14%) (Savage et al. 2011). Although 47 different species from 6 families were sampled from 11 different localities across western peninsular Malaysia at a diversity of elevations, sample sizes were too small to assess meaningful differences among sites, locations or elevations (Savage et al. 2011). We report surveillance data collected over three consecutive years (2008, 2009, and 2010) previous to the first documented *Bd*-positive samples in Peninsular Malaysia. In our surveys, we first observed *Bd* in 2010 but we were unable to detect *Bd* in Peninsular Malaysia prior to this year.

Amphibian swab samples were collected over a three year period from 2008 to 2010 using the British Columbia Ministry of the Environment *Bd* surveillance protocol (http://www.env.gov.bc.ca/wld/frogwatch/ecology/diseases.htm). All samples were of adult amphibians except for two small metamorphosed juvenile frogs in 2010.

Amphibians were opportunistically sampled from different locations in Peninsular Malaysia and from a diversity of habitats and ecosystems (Fig. 1). Only one site was sampled in 2008 (18 samples), two sites were sampled in 2009 (47 samples), and 11 sites were sampled in 2010 (98 samples). There were 5 sites sampled from 2009 through 2010 at palm oil plantations (177 samples; AF). All other field sites were sampled by Universiti Sains Malaysia researchers in association with the University of Victoria tropical field school program. The samples were collected from 4 m to 272 m elevation (Table 1) and sample sites encompassed different habitats: urban areas, palm oil plantations and forested regions (Table 1).

The samples were assayed using a TaqMan based qPCR approach to assess the presence of *Bd* (Boyle et al. 2004). The TaqMan quantitative PCR was performed on a Stratagene Mx4000 qPCR machine (Stratagene, Santa Clara, California, USA). The primers and probe used are outlined by Boyle et al. (2004). Each of the qPCR reactions was performed in triplicate using serial dilutions of positive control *Bd* strain, JEL 423, as well as a blank sample.

All amphibians sampled were native to Peninsular Malaysia except for two American Bullfrogs, *Lithobates catesbeianus* (Table 1) collected in 2010 in the Bukit Mertajam region of Penang, located on the northwest coast of Peninsular Malaysia. The only species which appeared on the International Union for Conservation of Nature's (IUNC) red-list for endangered species was the near-threatened species *Limnonectes blythii*. The survey also included five other species, *Hylarana glandulosa*, *Hylarana picturata*, *Humerana miopus*, *Hylarana nigrovittata*, *Xenophrys aceras*, which are believed to be decreasing in population size and many others which had insufficient data for conservation status assessment (www.iucnredlist.org). The only positive *Bd* sample was from an adult *Leptobrachium hendricksoni*, sampled in 2010 in the state of Perlis in the northwest of Peninsular Malaysia near the border with Thailand.

Our amphibian survey demonstrated only a single positive sample for *Bd* in 2010 after a three-year period of testing beginning in 2008. The survey published by Savage et al. (2011) demonstrated the presence of *Bd* in samples collected in March 2010. One possible explanation for this discrepancy is that *Bd* may have only recently emerged in Peninsular Malaysia and is now beginning to spread across the country. There have been relatively few studies which have examined the speed at which *Bd* can spread through a region which makes it difficult to explain the differences between the two studies (Lips et al. 2006; Lips et al. 2008). At some locations our study was unable to sample adequate numbers of amphibians to determine

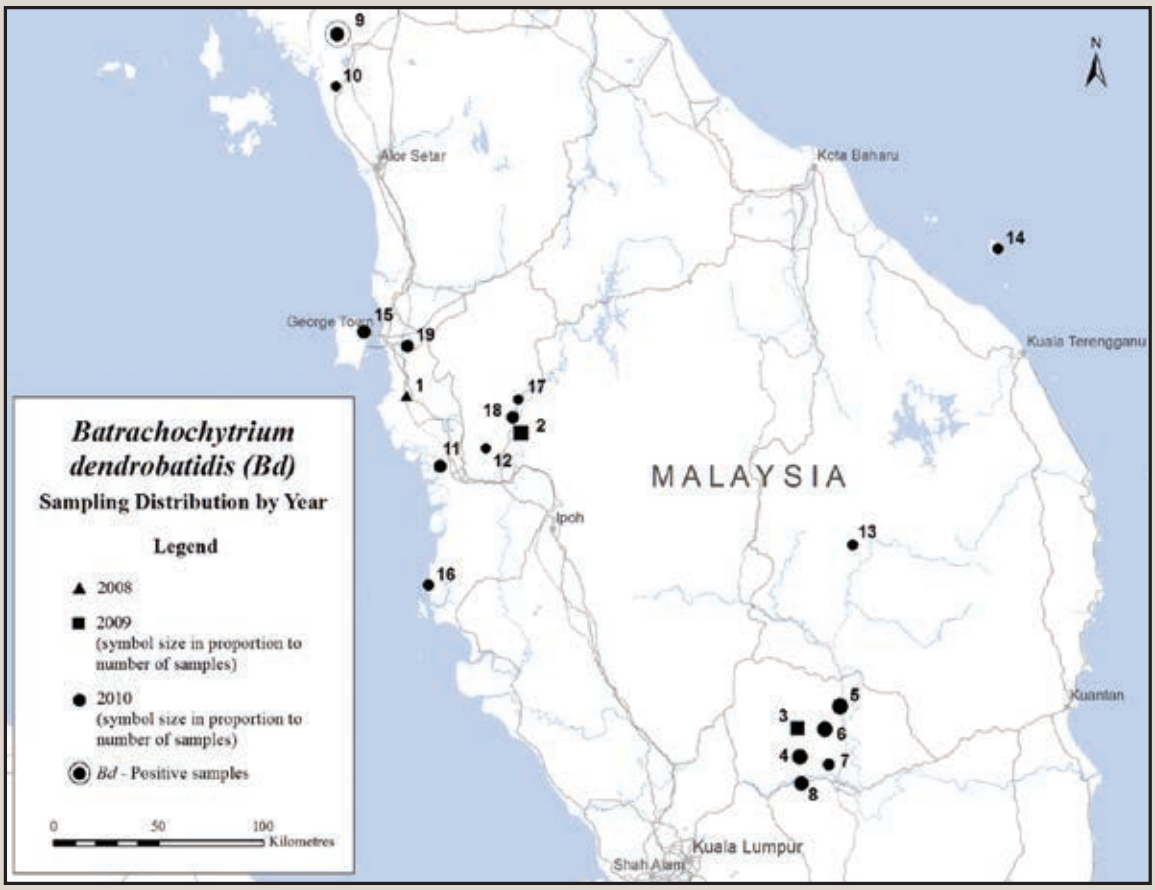

FIG. 1. Distribution of *Batrachochytrium dendrobatidis* (Bd) sample locations in Peninsular Malaysia. The relative size of the symbol indicates sample size. Numbers corespond to locations indicated in Table 1.

conclusive presence or non-detection of *Bd* (e.g., samples with more than 59 animals, Skerratt et al. 2008). The most significant difference between the two studies which may contribute to our results is that the sampling was performed at different altitudes and seasons. Our sampling typically occurred in the month of May or later while Savage et al. (2011) sampled in March which is typically cooler and more suitable for *Bd* growth (Piotrowski et al. 2004). In tropical regions *Bd* has been shown to be found at higher elevations due to the preferred temperature range for this pathogen (Berger et al. 1998; Pounds et al. 2006; Lips et al. 2008). Most of our sites were around 100 m or below, and the survey by Savage et al. (2011) found only two of their ten positive *Bd* detections below 100 m. The only positive *Bd* detection in our survey occurred at the highest elevation site (Table 1). The one positive *Bd* sample out of six amphibian samples found in neighboring Thailand was found at a site around 100 m elevation in August (mean annual temperature 28.3°C [Vörös et al. 2012]).

The geographic area covered by Savage et al. (2011) and our survey was similar. Our lone positive sample was taken in Perlis which was the only state without positive samples in the Savage et al. (2011) survey. However, their detection probability was very low given that there were only four samples from this state. Twenty of our 27 species overlapped with the Savage et al. (2011) survey but low samples sizes in both studies precludes species specific comparisons (Baláž et al. 2013). The positive amphibian in our study, *Leptobrachium hendricksoni*, was also found to be positive in the neighboring state by Savage et al. (2011). Although the two bullfrogs captured in our study were *Bd* negative, the area where these bullfrogs were captured had positive samples in the study done by Savage et al. (2011). The bullfrog is a likely candidate for the world-wide transmission of *Bd* as it is heavily traded in the amphibian market (Fisher and Garner 2007; Schloegel et al. 2009) and is largely asymptomatic (Daszak et al. 2004; Schloegel et al. 2010). Bullfrogs are widely available in live food markets in many Asian countries including Malaysia (Fisher and Garner 2007; Schloegel et al. 2009; Kolby et al. 2014), and may escape or be released into local ecosystems to serve as vectors for *Bd* introduction.

The recent increase in *Bd* surveillance around the world has led to the pathogen being detected in many new countries (Yang et al. 2009; Bai et al. 2010; Savage et al. 2011). The determination of whether this pathogen is endemic or has recently spread to regions in Malaysia will require a more systematic approach to surveillance. Exhaustive multi-year surveys may not be an option for all regions. Information may be gained by assessing historical specimens in museums in order to ascertain when an introduction event had occurred (Weldon et al. 2004; Lips et al. 2008; Soto-Azat et al. 2009; Lips et al. 2011). For well-established and persistent infections the origins of a pathogen may be established by the population genetic structure of the pathogen (Goka et al. 2009; Morgan et al. 2007; James et al. 2009; Farrer et al. 2011). The differences in prevalence values in the survey done by Savage et al. (2011) and our survey suggests that more research is needed to determine the origin of the pathogen in Peninsular Malaysia.

TABLE 1. Sampling site information and amphibian species tested for *Batrachochytrium dendrobatidis* (*Bd*) in Peninsular Malaysia from 2008 through 2010. Positive samples (*Bd*+), total sample size (N), elevation, and prevalence with 95% confidence intervals are indicated. Numbers before site names correspond to location numbers in Fig. 1.

Detection of a Frog Virus 3-like Ranavirus in Native and Introduced Amphibians in the United Kingdom in 2007 and 2008

Ranaviruses are considered to be emerging pathogens of amphibians in Europe (Duffus and Cunningham 2010). In the United Kingdom (UK) a frog virus 3 (FV3)–like ranavirus began to emerge in the mid- to late-1980s in populations of Common Frogs (*Rana temporaria*) in the southeast of England (Cunningham et al. 1996), followed closely by cases of infection and disease in some Common Toads (*Bufo bufo*) (Hyatt et al. 2000). Populations of Common Frogs have experienced declines as a result (Teacher et al. 2010). Most investigations of ranavirus in the UK have focused solely on Common Frogs (e.g., Duffus et al. 2013), but there are other species in the UK that are known to be susceptible to ranavirus infections such as larval Common Midwife Toads (*Alytes obstetricans*) and Alpine Newts (*Mesotriton alpestris*), both of which are introduced species in the UK (Balseiro et al. 2009, 2010), and adult Common Toads (Cunningham et al. 2007), a native species. The infection status of these other potential hosts has not been investigated in the UK. Understanding the infection status of syntopic amphibian species is important because ranaviruses are generalist pathogens (e.g., Mao et al. 1999; Schock et al. 2008). Additionally, some of the syntopic species that may be susceptible to the virus are of special interest, such as the Great Crested Newt (*Triturus cristatus*), a European Protected Species and a Herpetile Species of Priority in the UK and the Common Toad, also a Herpetile Species of Priority in the UK (JNCC 2007). The generalist nature of ranaviruses makes it important to investigate all potential amphibian hosts so that we may better understand

TABLE 1. Presence of the amphibian ranavirus in native and introduced species opportunistically sampled in the UK in both 2007 and 2008. N+ is the number of ranavirus positive individuals, whereas N is the total number of individuals screened. CI is the confidence interval of the proportion N+/N.

	2007		2008	
Species	N+/N	CI	N+/N	CI
Common Toad (*Bufo bufo*)	1/52	0.001–0.1158	0/23	0–0.1781
Great Crested Newt (*Triturus cristatus*)	0/2	0–0.8021	0/13	0–0.2834
Alpine Newt (*Mesotriton alpestris*)	0/4	0–0.6042	—	—
Common Newt (*Lissotriton vulgaris*)	1/17	0.0031–0.3776	1/18	0.0029–0.2938
Common Midwife Toad (*Alytes obstetricans*)	—	—	1/1	0.0546–1

the ecology of the ranavirus present in the UK and better inform conservation and management plans. Here we investigated the infection status of several native and introduced amphibian species in the UK for ranavirus.

In 2007 and 2008 we obtained dead animals opportunistically through citizen reports of mortalities made to Froglife (Registered Charity No. 1093372 in England and Wales, and No. SC041854 in Scotland) and to A.L.J.D., as well as by directly collecting specimens for ranavirus screening. A.L.J.D. arranged for whole carcasses to be delivered for complete post-mortem examination. Any animals that were alive when collected by us were euthanized according to Home Office Schedule One procedures by an overdose of MS-2,2,2 (tricane methylsulfonate, Thompson and Joseph Ltd, Norwich, UK) buffered to pH 7 with sodium bicarbonate. We followed the procedures for DNA extraction from hepatic tissues and PCR screening for ranaviral DNA described in Duffus et al. (2013). The geographic origins of some submitted samples are unknown, but we are certain that in 2007 Common Toads were collected from a minimum of three sites, Common Newts were collected from a minimum of two sites, Great Crested Newts from a minimum of two sites, and Alpine Newts were collected from one site. In 2008, Common Toads and Common Newts were collected from a minimum of different two sites, Great Crested Newts were collected from one site, as was the Common Midwife Toad.

The one adult Common Midwife Toad in our study was infected. It was collected at a garden pond in Brighton, Sussex (on the southeastern coast of England), during a mass mortality of Common Frogs and Common Toads (see Beebee 2012). The mortality in the Common Frogs at this site was associated with a ranavirus infection (Brighton site in Duffus et al. 2013). Common Midwife Toad tadpoles have been involved in mass mortality events associated with outbreaks of the Common Midwife Toad virus (CMTV) in Spain (Balseiro et al. 2009, 2010), but this is the first known infection in an adult of this species with ranavirus. This result underscores the importance of examining all life history stages for the presence of amphibian ranaviruses during a mass mortality event.

We also report the first ranavirus infection in a Common (Smooth) Newt (*Lissotriton vulgaris*). This newt was collected from a mortality event in 2007 that involved only adult Common Newts. However, since only one asymptomatic individual of 12 individuals screened from this event was positive for the presence of ranavirus, it is unlikely that the pathogen was responsible for the mortality event. The other five Common Newts screened in 2007 were from a site where the virus had a long history of infection in the Common Frog population (Teddington site in Duffus et al. 2013, southwest of London). During the collection of the Common Newts, the Common Frogs at the site displayed signs of active ranavirosis (A.L.J.D., pers. obs.). One of these five newts collected displayed large amounts of subcutaneous edema, a sign of ranavirosis in Common Frogs (A.L.J.D., pers. obs.), but none were positive for the ranavirus. Unfortunately, the origin of the one infected Common Newt collected in 2008 was unknown. Prior to Balseiro et al's 2009 report of a mass mortality event of larval Alpine Newts (*Mesotriton alpestris cyreni*) there were no reports of ranavirus infections in European urodeles. The infection that we report in Common Newts is thus the earliest documented occurrence of ranavirus infection in European urodeles.

We also screened for, but did not detect, ranavirus infections in Great Crested Newts, a native species, and Alpine Newts, an introduced species known to be susceptible CMTV (Balseiro et al. 2009, 2010). The Great Crested Newts that were collected in 2008 from a mass mortality event in this species from a site near York in the north of England, but were free of signs of ranavirus infection and tested negative for ranavirus DNA.

In our survey, only one of 52 Common Toads screened had a ranavirus infection. Ranavirus infection and associated mortality has previously been described in UK Common Toad populations (Hyatt et al. 2000). The emergence of the ranavirus in Common Toads has been put forward as an explanation for the widespread population declines observed in this species in the UK (e.g., Cunningham et al. 2007). However, if the emergence of ranavirus was a substantial cause of decline we would have expected more reports of mortalities associated with ranavirus infection. More thorough investigations are needed before a link between the emergence of the ranavirus and the population declines of Common Toads in the UK can be properly made.

Our current report shows that the ranavirus infects at least three additional species in the UK. Understanding the host range of the ranavirus(es) in the UK is a necessary step in the formation and implementation of conservation and management plans of both native and introduced amphibian species. Further studies are needed to understand the geographic distribution of the ranavirus in all potentially susceptible amphibian species in the UK. Experimental determination of the susceptibility of native and introduced species would be very helpful in understanding the dynamics of the pathogen at a European level.

Acknowledgments.—Funding for this work was provided by the following grants to ALJD: Queen Mary University of London

International Graduate Studentship, Queen Mary University of London Research Studentship, Natural Science and Engineering Council of Canada 3 year Doctoral Awards, Central Research Fund Graduation Award (University of London), and a British Wildlife Trust Student Award. Funding was also provided through a RCUK Fellowship awarded to TWJG. Special thanks to the pond owners and the South Essex Wildlife Hospital. Thank you to J. C. George, two anonymous reviewers, and J. L. Brunner for their comments on this manuscript that greatly improved its quality.

Amphibian Chytrid Infections in Non-forested Habitats of Katanga, Democratic Republic of the Congo

Numerous studies have documented the presence of the amphibian chytrid fungus *Batrachochytrium dendrobatidis* (*Bd*) in a diverse array of anuran and caecilian species from central, eastern and southern Africa (reviewed in Greenbaum et al. in press). The majority of previous surveys for *Bd* in Africa have focused on forested habitats, and with the exception of South Africa, large areas of non-forested regions of Africa remain unstudied (Olson et al. 2013). Studies that sampled for *Bd* presence in non-forested regions of Central Africa are especially sparse, and few positive records are known (Olson et al. 2013). The largest data set near the region (www.bd-maps.net/) presented 68 samples with no detected chytrid infection in 16 species of amphibians from eight localities in southeastern Zambia. The website also reported a single positive record of a *Xenopus laevis* from a nearby site in Malawi.

Katanga Province (just under 500,000 km^2) is located in southeastern Democratic Republic of the Congo (DRC), and is bordered by Angola and Zambia (Bobb 1999). Most of the province contains vegetation associated with the Central Zambezian Miombo Woodland Ecoregion (*sensu* Burgess et al. 2004), but the southern extent of the Albertine Rift (containing grasslands and some tiny forest patches) extends along the eastern border of the province at Lake Tanganyika. Although some recent herpetological work has occurred in the region (e.g., Greenbaum et al. 2010, 2012a,b), few surveys have occurred since the colonial era (de Witte 1953; Laurent 1950, 1957; Plumptre et al. 2007; Schmidt and Inger 1959). Despite the "sporadic and patchy" surveys of Katanga's biodiversity in general, Broadley and Cotterill (2004) noted that at least parts of Katanga should be considered a biodiversity hotspot, based on its exceptional reptile endemism.

As part of an opportunistic herpetological inventory in Katanga Province, EG and CK visited 20 localities and collected 56 samples (from adult and post-metamorphic frogs only) for *Bd* analysis between 30 December 2009 and 21 January 2010 (Fig. 1). According to annual rainfall plots for cities in Katanga from Chapin (1932), our sampling period overlapped with the rainy season. Most of the surveyed areas were mid- to low-

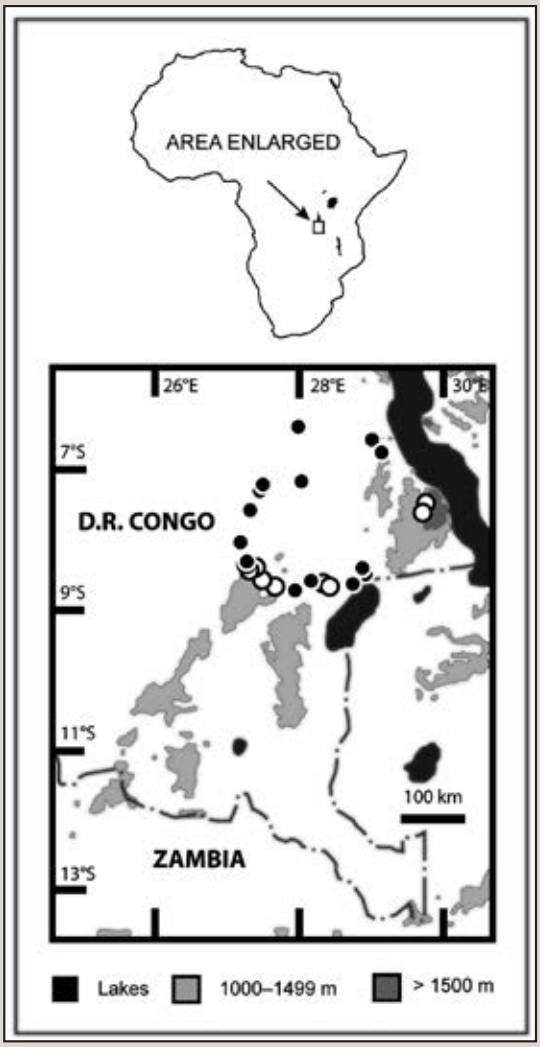

FIG 1. Sampling localities from Katanga Province, Democratic Republic of the Congo. Open circles represent localities with at least one *Bd*-positive sample, and closed circles are localities where *Bd* was undetected.

FIG. 2. Adult female *Hyperolius quinquevittatus* from Pepa, Democratic Republic of the Congo. This individual tested positive for *Bd*.

elevation woodland/savanna mosaic habitats, but the team also sampled villages, lakes, marshes and montane grasslands. Frogs were collected by hand (without gloves) after audio recording of male advertisement calls (in the case of calling males), or during opportunistic visual encounters. Frogs were temporarily stored in well-ventilated plastic containers immediately after capture. Rarely, some individuals of the same species (up to six) were housed in the same container for a few hours before swabbing. Plastic containers were disinfected with a 10% bleach solution after each collection event, minimizing the chance of cross contamination between collection events. While in their containers, a subset of captured individuals were swabbed with sterile swabs (MW100; Medical Wire & Equipment Co, Crosham, UK) for approximately 20 seconds on the ventral surfaces of the abdomen, throat, hands and feet. Swabs were stored individually and dry in shaded containers away from direct sunlight and heat in the field, and transferred to 4°C freezers upon arrival to the laboratory. The QIAmp DNA Mini Kit (Qiagen, Hilden, Germany) was used to extract DNA (manufacturer's protocol) from these swabs. Real-time PCR was performed on a LightCycler 480 (Roche Applied Science, Indianapolis, IN, USA) with the protocol of Boyle et al. (2004), with *Bd* primers specific to the ITS-1/5.8S region of the ribosomal gene. DNA extracted from *Bd*-positive cultures was used as a positive control, and amplicons from two positive frog samples were sequenced to confirm the specificity of the amplification products. We considered samples to be positive if they showed distinct sigmoidal amplification in the real-time PCR, because negative samples and controls do not display this amplification pattern (Soto-Azat et al. 2010).

A total of 56 frogs representing 32 species were swabbed during this study, and 16 of these individuals were *Bd*-positive, for an overall *Bd* prevalence of 28.6% (Table 1). The genera *Afrixalus*, *Amietophrynus*, *Hemisus*, *Hildebrandtia*, *Hoplobatrachus* and *Schismaderma* did not include any positive individuals. Among the remaining genera, *Arthroleptis*, *Leptopelis* and *Kassina* had one *Bd*-positive species each (100% prevalence), *Amietia* was positive for two of three species (66.7% prevalence within the genus), *Xenopus* was positive for one of two species (50% prevalence), *Hyperolius* was positive for three of seven species (42.9% prevalence, Fig. 2), *Phrynobatrachus* was positive for one of three species (33% prevalence), and *Ptychadena* was positive for one of five species (20.0% prevalence). Sample sizes within species were mostly low, and included only a single individual for 19 species, two individuals for five species, and three individuals for seven species. Only *Arthroleptis* cf. *stenodactylus* had a larger sample size, with two of six individuals testing positive for *Bd* (33.3% prevalence). Among the 20 localities visited during the study, eight (40%) contained *Bd*-positive frogs (Fig. 1). Only four of these sites were sampled for five or more species, and with the exception of Pepa (100% prevalence), *Bd* prevalence among the species in these sites was low (Pweto, 0% prevalence; Kabongo, 16.7% prevalence; 7 km S of Manono, 0% prevalence). No dead, dying, or morbid frogs were encountered during the survey.

Several studies have documented the relatively high *Bd* infection rates in amphibian populations that are endemic to cool, montane habitats (e.g., Gower et al. 2012; Pounds et al. 2006; Stuart et al. 2004; but see Olson et al. 2013), and all species and localities sampled from the Marungu Plateau (> 1950 m elev.) in our study were positive. The genus *Amietia* is especially vulnerable to *Bd* infection because it is a prominent member of stream-breeding, montane amphibian faunas in eastern, central and southern Africa (Frost 2014), and we confirmed the

TABLE 1. Summary of *Batrachochytrium dendrobatidis* infections in multiple species of frogs from Katanga Province, Democratic Republic of the Congo, during a three-week opportunistic survey from December 2009 to January 2010.

genus had a high prevalence of infection in Katanga Province. Our results are consistent with several other studies that have documented *Bd* infections in *Amietia* populations elsewhere in Africa (Conradie et al. 2011a,b; Greenbaum et al., *in press*; Kielgast et al. 2010; Viertel et al. 2012; Zancolli et al. 2013). The relatively low prevalence of *Bd* infection in the presumably direct-developing species *Arthroleptis* cf. *stenodactylus* in Katanga is also consistent with previous studies that tested *Arthroleptis* (Bell et al. 2011; Conradie et al. 2011a; Doherty-Bone et al. 2013; Olson et al. 2013) and the presumably direct-developing genus *Balebreviceps* in Ethiopia (Gower et al. 2012).

With the exception of *Hemsius wittei* and *Hyperolius nasicus* (both data deficient), all other recognized species in our study are considered to be "least concern" under the IUCN Red List Criteria (IUCN 2013). However, 18 of the taxa we studied (labeled as "cf." or "sp." in Table 1) are genetically and/or morphologically distinct from their closest named relatives (EG, unpubl. data), and are likely to be threatened because of relatively small geographic distributions. Like many other surveys for *Bd* in Africa (reviewed in Greenbaum et al., *in press*), we did not find any dead or dying frogs, suggesting chytridiomycosis was not causing massive "die offs" in Katanga during the time of this study. As first documented by Greenbaum et al. (*in press*) in the Albertine Rift of DRC, several *Bd*-positive frogs (*Hyperolius* cf. *kivuensis*, *H. nasicus* and *Kassina* cf. *senegalensis*) in Katanga were calling for mates. The parasite load of these calling males is unknown (see below), but it is unlikely that they could expend the energy to attract mates if their infections were severe.

Because our sampling was opportunistic and sample sizes for species and localities were relatively low, it is likely that some *Bd*-positive frogs were not detected in our study (Skerratt et al. 2008). We acknowledge that our results could have been affected by the lack of gloves during capture of frogs in the field, or by housing individuals of the same species together. However, because there are some cases in our data set where *Bd*-negative frogs were collected after *Bd*-positive frogs during a given collection event, the possibility of cross contamination during capture is likely minimal (see also Greenbaum et al., *in press*). We did not attempt to calculate zoospore genomic equivalent estimates, which precludes comparisons of parasite loads to some previous studies. Our results (and probably many other previous studies—see Zancolli et al. 2013) were likely affected by unavoidable exposure of stored swabs to high temperatures (as high as 45°C ambient temperature) during transportation between field sites. Van Sluys et al. (2008) demonstrated that high temperatures can significantly decrease the ability of PCR-based assays to detect *Bd* fungus and quantify associated zoospore loads. Because of these concerns and likely seasonal fluctuations in *Bd* infection (e.g., Conradie et al. 2011b), we recommend that future surveys test Katanga amphibians during cooler times of the year. Given the large number of endemic amphibian species in Katanga (Laurent 1957; Schmidt and Inger 1959; Poynton 1998) and the confirmed presence of *Bd*-positive frogs in the region, additional monitoring should continue to ensure that Katanga's amphibian populations are stable.

Acknowledgments.—Fieldwork by EG in DRC was funded by the Percy Sladen Memorial Fund, an IUCN/SSC Amphibian Specialist Group Seed Grant, Department of Pathology at Northwestern University Feinberg School of Medicine, Department of Biology at Villanova University, a National Geographic Research and Exploration Grant (no. 8556-08) and UTEP; EG and CK thank their field

Prevalence of *Batrochochytrium dendrobatidis* in Three Frog Species of the Bighorn National Forest, Wyoming, USA

We determined the prevalence of *Batrochochytrium dendrobatidis* (*Bd*) in three species of conservation concern, *Lithobates pipiens*, *Rana luteiventris*, and *Lithobates sylvaticus*, in the Bighorn National Forest, Wyoming, USA (Fig. 1). The Bighorn Mountains in north-central Wyoming consist of over 450,000 ha of national forest, ranging in elevation from 1500 to 4000 m (http://www.fs.usda.gov/main/bighorn). The Bighorn National Forest is a geographically isolated region that includes a variety of aquatic habitats, such as lakes, ponds, and marshes. The Northern Leopard Frog (*Lithobates pipiens*) has shown distinct range reduction (thought to be caused by habitat degradation and urbanization) in a portion of the range that includes Wyoming, making the Northern Leopard Frog a species of conservation concern (Smith and Keinath 2007). Populations of Columbia Spotted Frog (*Rana luteiventris*) in the Bighorn Mountains are of conservation concern because the species exists as relict populations which are genetically isolated and distinct from the rest of the species' range (Dunlap 1977; Patla and Keinath 2005). The Wood Frog (*Lithobates sylvaticus*) is of conservation concern in Wyoming because it occurs as relict, genetically isolated populations in the Bighorn Mountains, where it is known from only a few localities (Dunlap 1977; Muths et al. 2005). Results of our study will aid future management decisions in the Bighorn National Forest for these three species.

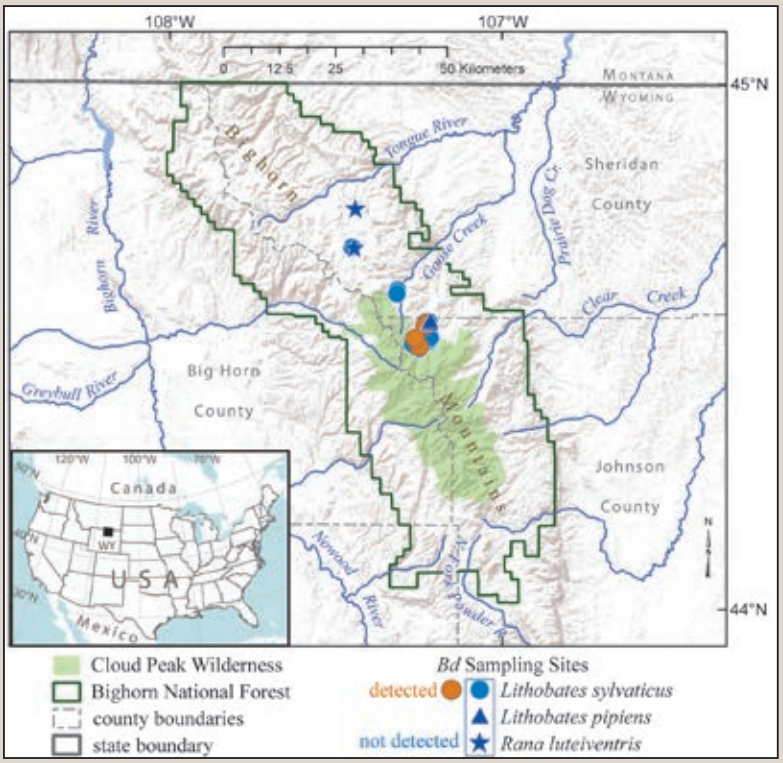

FIG. 1. Locations and infection level of *Lithobates sylvaticus, Lithobates pipiens,* and *Rana luteiventris* in the Bighorn National Forest, Wyoming, USA.

We conducted amphibian surveys from 3–16 August 2010 in the northern portion of the Bighorn Mountains, Johnson County, Wyoming. The majority of the study area was within the northern portion of the Cloud Peak Wilderness of the Bighorn National Forest. The study site included four localities comprised of six previously known frog sites (Dunlap 1977) and 38 new sites within the Cross Creek, Big Goose Creek, and Edelman Creek drainages and surrounding areas. We surveyed ponds, lakes, and wet meadows that were discovered opportunistically or upon review of topographic maps.

We captured metamorphic, sub-adult, and adult frogs by hand or by dip net. Upon capture, we identified species, measured body length (mm) using a ruler, determined age class based on body length reports from the literature, and determined sex based on the presence of nuptial pads on adult males. We swabbed frogs for *Bd* according to the Colorado Division of Wildlife Protocol (Livo 2004). To prevent cross-contamination, we used sterile technique, including changing gloves between captures and disinfecting all equipment between sites according to the Colorado Division of Wildlife Protocol (Livo 2004). We returned samples to Truman State University for analysis using a nested polymerase chain reaction (PCR) adapted from Gaertner et al (2009). We included one positive and one negative control reaction per eight samples for both rounds of PCR, and presence of a 300 bp band in a field-collected sample indicated an individual infected with *Bd*.

We captured and swabbed 107 Wood Frogs, 30 Columbia Spotted Frogs, and four Northern Leopard Frogs. Infection level varied across species, with zero spotted and leopard frogs infected and 6.5% (7/107) Wood Frogs infected (Fig. 1). Within Wood Frogs, there was no significant effect of elevation (Regression; $F_{1,104} = 1.16$, $p = 0.284$), sex (Fisher's Exact Test; OR = 1, $p = 0.313$), or age class (Fisher's Exact Test; OR = 0.426, $p = 0.663$) on *Bd* infection. During field sampling, we did not observe any animals with symptoms of the disease chytridiomycosis.

Overall, within the Big Horn National Forest, Wyoming we detected a relatively low level of *Bd* infection in the three native frog species with conservation concern. However, with only four leopard frogs sampled, it is possible for a relatively high infection

rate to go undetected (Skerratt et al. 2008). The low rate of infection in Wood Frogs, for which we had a more robust sample, is encouraging for the species. Nevertheless, monitoring of these geographically isolated populations is recommended because the disease-host dynamics are not well known and these animals represent unique diversity.

Acknowledgments.—This study was conducted as part of a field course through Truman State University. All research was approved by the Wyoming Game and Fish Commission permit to CEM and the United States Forest Service and was conducted in accordance with Truman State University IACUC guidelines. We thank D. Patla, Z. Walker, B. Bornong, J. Gardner, L. Dickerson, and H. Golden for assistance in the field and logistical support. We thank E. Brochschmidt, M. Mueller, and J. Plaggenberg for assistance in the laboratory. We also thank K. Ronnenberg for developing the location and infection level map.

First Record of *Batrachochytrium dendrobatidis* in the Arizona Toad (*Anaxyrus microscaphus*) in Southwestern New Mexico, USA

The fungal pathogen *Batrachochytrium dendrobatidis* (*Bd*), which causes the disease chytridiomycosis, is geographically widespread across the United States (Lannoo et al. 2013; Olson et al. 2013). Chytridiomycosis has caused the decline of some North American species (e.g., Southern Mountain Yellow-legged Frog, *Rana muscosa*; Briggs et al. 2010; Vredenburg et al. 2010), yet other species seem relatively unaffected by *Bd* infection (e.g., American Toad, *Anaxyrus americanus*; Longcore et al. 2007). Many arid and desert-adapted amphibian species in the southwest U.S. such as *Rana chiricahuensis*, (Chiricahua Leopard Frog) have experienced declines and are now considered to be high conservation priorities (Bradley et al. 2002; Schlaepfer et al. 2007; Olson et al. 2013). The role of chytridiomycosis in these declines has not been determined but is important to resolve in order to identify vulnerable species that require conservation intervention.

Within New Mexico, four amphibian species have declined to critically low levels: *R. chiricahuensis, R. pipiens* (Northern Leopard Frog), *R. yavapaiensis* (Lowland Leopard Frog), and *Anaxyrus boreas* (Western Toad). In neighboring states where these species occur, declines have been attributed to chytridiomycosis (Bradley et al. 2002; Muths et al. 2003; Lannoo et al. 2011); hence it is suspected that *Bd* is contributing to the New Mexico declines as well. Recent investigations have found that 53% (9 of 17) of tested species of New Mexican amphibians have tested positive for *Bd* (Painter et al., unpubl.), but there is still not a clear understanding of the distribution and prevalence of *Bd* in New Mexican amphibians (Olson et al. 2013; Painter et al., unpubl.).

The Arizona Toad, *Anaxyrus microscaphus* (Fig. 1), is a riparian species that occurs in scattered populations in Arizona, Nevada, Utah, and New Mexico (Schwaner and Sullivan 2005). Previous studies have indicated that declines of *A. microscaphus* may be due to hybridization between *A. microscaphus* and *A. woodhousii* (Woodhouse's Toad) in Arizona, Nevada, and Utah (Sullivan 1995; Schwaner and Sullivan 2009) and altered water

FIG. 1. An adult *Anaxyrus microscaphus* calling along Little Creek, New Mexico, USA on 29 March 2013.

flow regimes from dam construction and habitat modification (Bradford 2002; Hammerson and Schwaner 2004). To date, *Bd* has not been detected in *A. microscaphus*, and it is unknown if *Bd* poses a yet unrecognized threat to this species.

During a 2013 study of *A. microscaphus* in southwestern New Mexico, we sampled 25 *A. microscaphus* for *Bd* from four sites in the Gila National Forest (Fig. 2): Hells Hole (33.787°N, 108.694°W; 1915 m elev.; Catron Co., nine samples), San Francisco River (33.344°N, 108.902°W; 1461 m elev.; Catron Co., two samples), Little Creek, (33.194°N, 108.220°W; 1724 m elev.; Grant Co., 12 samples), and the upper Mimbres River (33.040°N, 107.980°W; 2081 m elev.; Grant Co., three samples) (Fig. 2). In addition, we monitored *A. microscaphus* at Little Creek weekly from 28 March to 15 May 2013. Previously, 11 years earlier, on 3 June 2002, following a mass die-off of the threatened species *R. chiricahuensis*, two *A. microscaphus* individuals were sampled for *Bd* at the die-off location in the vicinity of Six-shooter Tank (33.518°N, 108.699°W; 2430 m elev.). Following standardized field protocols, we collected and stored *Bd* swab samples in 95% ethanol and a -80°C freezer until processing (Boyle et al. 2004; Hyatt et al. 2007). Samples were submitted in batches of six to Pisces Molecular Laboratory (Boulder, Colorado, USA) for pooled analyses of *Bd* DNA using qPCR.

Bd was detected from one of two batch samples of *A. microscaphus* collected from Little Creek (collected on 29 March 2013). Samples from Hells Hole, upper Mimbres River, and San Francisco River were *Bd*-negative. One *Bd*-positive *A. microscaphus* individual was found at the site of the 2002 die-off of *R. chiricahuensis*. During the March to May 2013 field observations of *A. microscaphus* at Little Creek site, we observed breeding activity among a maximum of 21 toads (15 males, 6 females), including male calling, and pairs in amplexus and laying eggs. We did not observe sick or dead *A. microscaphus* during this monitoring, or during handling for swab collection and measurements at any location.

These *Bd*-positive results from New Mexico are the first records of *Bd* in *A. microscaphus*. Both records are from the Gila National Forest, which encompasses much of the range of *A. microscaphus* in New Mexico (Degenhardt et al. 1995). *Bd* was previously detected on amphibians in the Mogollon Rim of Arizona and New Mexico (Painter et al., unpubl.).

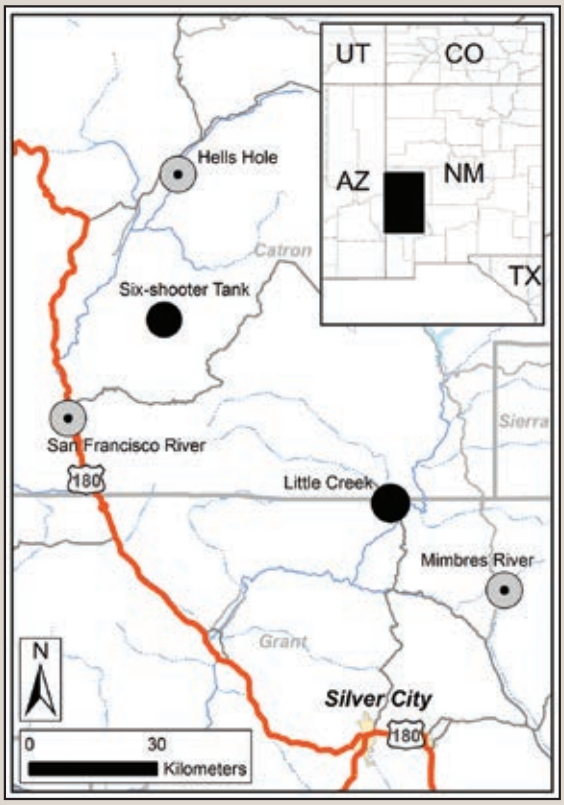

FIG. 2. Distribution of localities in two counties of southwestern New Mexico from which Arizona Toads *(Anaxyrus microscaphus)* were examined for *Batrachochytrium dendrobatidis (Bd)*. Filled circles indicate sites that tested positive, whereas open circles with a dot indicate sites where *Bd* was not detected.

Although *Bd* has been detected in its range, the role of *Bd* in population declines of *A. microscaphus* remains unknown. Populations of *A. microscaphus* have declined in areas of New Mexico where hybridization and altered stream flows from water impoundments are not a threat (Ryan et al., unpubl.), and remain enigmatic. To our knowledge, no mass die-offs characteristic of a *Bd* outbreak have been observed in *A. microscaphus* in Arizona and New Mexico (Bradley et al. 2002), but the possibility of *Bd* as a threat cannot be ruled out. Further studies utilizing museum specimens and reviews of unpublished data and reports may fill in gaps of possible die-offs and the prevalence of *Bd* in *A. microscaphus*.

Acknowledgments.—The New Mexico Department of Game and Fish and Share With Wildlife Program kindly funded this work and issued permits. We thank the Museum of Southwestern Biology and University of New Mexico for logistical support. We thank Dede Olson, Carmen Hope, and Natalie Hambalek for providing valuable comments to this paper. All research was conducted in accordance with the University of New Mexico IACUC guidelines.

On the Thermal Husbandry of Monitor Lizards

Thermal husbandry, the range of temperatures offered to reptiles in captivity, is one of the most basic, yet critical aspects of herpetological husbandry. As poikilothermic ectotherms, reptiles are unable to physiologically maintain constant body temperatures and must instead thermoregulate behaviorally by utilizing the range of temperatures available to them within their environment (Cowles and Bogert 1944; Bogert 1949, 1959). Because reptiles vary considerably in their thermal tolerances, preferences and thermoregulatory strategies, providing taxon-specific husbandry consistent with a species' ecology and thermal biology should be a primary focus of reptile collections and caregivers (Peaker 1969; Arena and Warwick 1995; Lillywhite and Gatten 1995). Although the general importance of providing appropriate thermal gradients in herpetological husbandry has long been emphasized (Peaker 1969; Arena and Warwick 1995), specific data on the thermal biology of most species are lacking, and as a result, captive environments may not provide the diversity and range of microclimates and microhabitats needed by reptiles to thermoregulate properly (Arena and Warwick 1995). Inappropriate thermal regimes, in turn, can have deleterious effects on the health and welfare of captive reptiles (Arena and Warwick 1995; Lillywhite and Gatten 1995).

Monitor lizards (family Varanidae, genus *Varanus*) occur throughout Africa, Asia, and Australia, and occupy a variety of habitats ranging from arid deserts to tropical lowland forests and mangrove swamps (Pianka and King 2004). Largely due to their size, activity levels, and observable intelligence, varanids are frequently maintained in zoos and private collections, where more than 55 species are currently kept in captivity (Eidenmüller 2007; Brown 2012). Despite having been maintained in numerous collections dating back more than 150 years, captive varanids continue to present significant husbandry challenges, with both zoos and private collections experiencing limited long-term maintenance and reproductive success relative to the number of specimens that have been kept (Bennett 1989, 1994; Bennett and Thakoordyal 2003; Mendyk, unpubl.). Recent assessments suggest that many varanid species may not be reaching their full lifespan potentials in captivity (Mendyk, unpubl.), and several authors have identified and discussed problematic areas of their captive management and reproduction (Horn and Visser 1989; Boyer and Boyer 1997; Horn and Visser 1997; Hartdegen 2002; Spelman 2002; Horn 2004; Mendyk et al. 2013). Of the various factors known to affect the health and welfare of varanid lizards in captivity, inappropriate thermal husbandry appears to be one of the most significant, yet highly overlooked issues (Bennett and Thakoordyal 2003; Mendyk et al. 2013). Inadequate thermal husbandry may not be easily recognized or understood, and as a result, some zoos, private herpetoculturists, and research laboratories may not be providing captives with the appropriate conditions needed to thrive.

In this article, we review several aspects of the thermal biology of wild varanid lizards and discuss how these parameters may relate to, and influence their maintenance in captivity. From a historical perspective, we highlight a significant paradigm shift in their thermal husbandry, and discuss how changing attitudes towards their captive management over the last few decades have helped improve keeping and reproductive success. Lastly, we discuss the implications and potential consequences that inadequate thermal husbandry can have on biological research.

The Thermal Biology of *Varanus*

Varanids are unique among extant lizards regarding various aspects of their physiology. Relative to other reptile groups, varanids possess remarkably high aerobic capacities and unique lung morphology, with some of the highest rates of oxygen consumption documented among non-avian reptiles (Bartholomew and Tucker 1964; Bennett 1972; Earll 1982; Becker et al. 1989; Schachner et al. 2014). This, coupled with metabolic rates greater than many other reptiles and efficient behavioral control over heating and cooling, enables them to operate over a much wider temperature range and sustain greater activity levels than other lizards (Earll 1982; Auffenberg 1994; Thompson and Withers 1997; Thompson 1999; Sweet and Pianka 2007). The thermal biology of varanids has been a subject of much interest among researchers, and various aspects of their thermoregulation have been studied in depth through field (e.g., radiotelemetry, mark-recapture) and laboratory investigations over the past several decades (Bartholomew and Tucker 1964; Licht et al. 1966; Stebbins and Barwick 1968; Johnson 1972;

Brattstrom 1973; Sokolov 1975; McNab and Auffenberg 1976; Meek 1978; King 1980; Auffenberg 1981, 1988, 1994; Gleeson 1981; Buffenstein and Louw 1982; Earll 1982; King et al. 1989; Wikramanayake and Green 1989; Green et al. 1991; Thompson and Withers 1992, 1997; Wikramanayake and Dryden 1993, 1999; Christian and Weavers 1994; Traeholt 1995; Christian and Bedford 1996; Christian and Weavers 1996; Christian et al. 1996; Thompson 1997; King and Green 1999; Thompson et al. 1999; Walsh et al. 1999; Wikramanayake et al. 1999; Ibrahim 2000; Heger and Heger 2007; Smith et al. 2008; Harlow et al. 2010).

Field studies have shown that active varanid lizards have preferred, or average body temperatures (Tbs) which exceed those of many other lizard groups. With the exception of a few semi-aquatic species (*Varanus salvator*, *V. mertensi*, *V. niloticus* and *V. indicus*) which seem to prefer to maintain lower Tbs between 28.9 (84°F) and 34°C (93.2°F) (Wikramanayake and Green 1989; Traeholt 1995; Muhigwa 1998; King and Green 1999; Smith et al. 2008), the majority of varanid species looked at maintain optimal Tbs between 35 (95°F) and 39°C (102.2°F) (Licht et al. 1966; Stebbins and Barwick 1968; Pianka 1970, 1994a; King 1980; Vernet et al. 1988; King et al. 1989; Wikramanayake and Dryden 1993; Christian and Bedford 1996; Christian and Weavers 1996; King and Green 1999; Heger and Heger 2007), but for short periods can withstand core body temperatures above 40°C (104°F) (Auffenberg 1994; Pianka 1994a; King and Green 1999; King et al. 1999; Thompson et al. 1999; Ibrahim 2000). The critical thermal maximum - the core body temperature at which death occurs - has been studied in several species including *V. komodoensis*, *V. olivaceus* and *V. bengalensis*, and ranges between 41.6 (106.9°F) and 44.6°C (112.3°F) (McNab and Auffenberg 1976; Auffenberg 1981, 1988, 1994).

Although morphologically conservative, varanid lizards do exhibit considerable variation in body size between species, ranging in mass by nearly five orders of magnitude (Pianka 1995). Given this disparity, thermoregulation within the genus is heavily influenced by thermal inertia associated with body size (Brattstrom 1973; Harlow et al., 2010). Larger taxa, particularly *V. komodoensis*, semi-aquatic species such as *V. salvator*, *V. niloticus*, *V. mertensi*, and *V. indicus*, and dense forest-dwelling species such as *V. olivaceus* , typically maintain lower, but relatively stable body temperatures throughout the day and night (Auffenberg 1981, 1988; Wikramanayake and Green 1989; Wikramanayake and Dryden 1993; King and Green 1999; Smith et al. 2008). Adult individuals of some larger species can be independent of external heat input for several hours once their preferred Tbs are reached (Wikramanayake and Dryden 1993; Harlow et al. 2010), and some species can maintain relatively stable Tbs in nocturnal retreats and emerge the following morning with body temperatures warmer than ambient air conditions (Auffenberg 1981; Pianka and Vitt 2003). A lower thermal conductance in semi-aquatic species such as *V. salvator* is also believed to enable these animals to more effectively maintain stable Tbs while foraging, traveling, and sheltering in aquatic environments (King and Green 1999).

Not all larger varanids fit this general model. Adult *V. giganteus* (to 2 m in total length [TL]) and *V. bengalensis* (to 1.4 m TL) both experience considerable fluctuations in body temperature throughout the day (Wikramanayake and Dryden 1999; Heger and Heger 2007). In contrast to *V. komodoensis* and *V. salvator*, *V. bengalensis* and many smaller taxa have a higher thermal conductance which enables them to heat up and cool down more quickly, and also tend to experience greater daytime fluctuations in body temperature, that drop considerably at night (Wikramanayake and Green 1989; Wikramanayake and Dryden 1993; King and Green 1999). For this reason, smaller taxa and juveniles of larger species usually require a greater degree of shuttling between shaded and sunlit areas to achieve and maintain preferred Tbs throughout the day (King and Green 1999; Wikramanayake et al. 1999; Harlow et al. 2010).

To achieve and maintain body temperatures that are usually greater than that of the ambient air, varanids require access to fairly high surface basking temperatures (Pianka 1970). Although some varanids have been shown to increase body temperatures through metabolic activity (Bartholomew and Tucker 1964), such increases are negligible and not considered to be a significant factor in thermoregulation (Auffenberg 1981, 1988). As heliotherms, they typically elevate their body temperatures by increasing exposure to solar radiation, but also absorb significant conductive heat through physical contact with substrates, surfaces and shelters heated by the sun. Auffenberg (1994) noted that in open areas, radiation from heated substrates can have a greater impact on thermoregulation in varanids than solar radiation. Unfortunately, few field studies have investigated the actual surface temperatures selected by varanids for basking; therefore, specific data are scarce (Pandav and Choudhury 1996; Ibrahim 2000; Auliya 2006).

It is well established that daytime surface temperatures in sun-exposed environments inhabited by varanids usually exceed both ambient air temperatures and the animals' preferred body temperatures (Auffenberg 1981, 1988, 1994). For example, in open habitats utilized by *V. komodoensis*, daytime substrate temperatures can reach over 50°C (122°F) (Auffenberg 1981). In northern India, Auffenberg (1994) noted that ground temperatures in *V. bengalensis* habitat exceeded 60°C (140°F) for 72% of the species' activity period, and in varanid habitats of northern Australia, surfaces receiving full radiant energy from the sun can exceed 70°C (158°F) (Christian and Weavers 1996). While these temperatures would prove lethal if individuals were continuously exposed to them, varanids tend to only enter sunlit areas for brief periods for basking or while foraging. Wild *V. tristis orientalis* have been observed basking on rocks in exposed sunlit areas with recorded surface temperatures of 60°C (140°F) (J. Lemm, unpub. dat.), and wild *V. varius* have been observed basking atop sun-exposed leaf litter with recorded surface temperatures of 56°C (132.8°F) (D. Kirshner, pers. comm.; Fig. 1). Captive *V. semiremex* maintained outdoors under natural climatic conditions regularly sought out sunlit branches for basking, with surface temperatures as high as 56°C (132.8°F) (Jackson 2005). These limited data suggest that many varanid species select and utilize surface basking temperatures that are far greater than their preferential range of body temperatures.

Basking in exposed areas poses serious risks of predation for many heliothermic reptiles. Minimizing the time spent basking can be advantageous in terms of predator avoidance (Krebs 1999; Wikramanayake and Dryden 1999), and can also allow more time for other important activities such as foraging (Auffenberg 1988; Wikramanayake and Dryden 1999). Therefore, with access to a range of microhabitats and microclimates within their environment, varanids and other heliothermic reptiles can be expected to select greater temperatures for basking in order to facilitate a quicker transition to their optimal body temperatures (Krebs 1999).

Reptiles, including varanids, also regulate their body temperatures by seeking out cooler microhabitats. Accessing

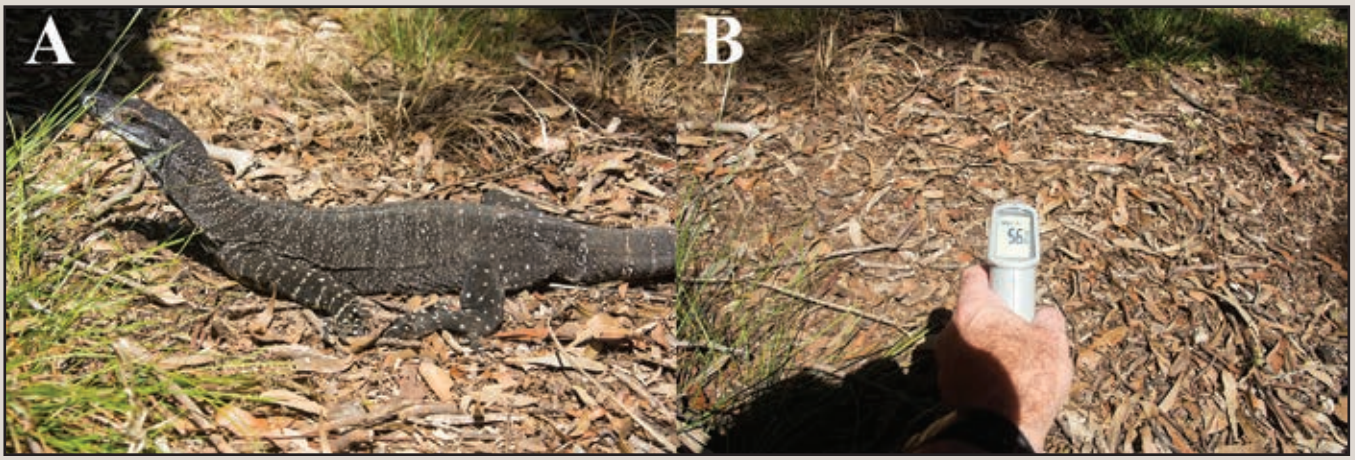

FIG. 1. A) Wild adult *Varanus varius* basking atop leaf litter in a forested area outside Sydney, New South Wales, Australia at 1500 h. B) Surface temperature of the basking site (56°C [132.8°F]; air temperature 26°C [78.8°F]) was recorded immediately after the lizard fled the area (D. Kirshner, pers. comm.).

cooler temperatures can serve as an energy-conserving measure (Huey and Stevenson 1979; Nagy 1983), a way to escape potentially life-threatening temperature extremes, or as a method of reducing evaporative water loss (Avery 1994). Depending on species and habitat, varanids employ various strategies for reducing body temperatures which include entering water (Auffenberg 1994; King and Green 1999; Auliya 2006), moving to shaded areas (Auffenberg 1994; King and Green 1999), seeking out breezy locations (Auffenberg 1994; Heger and Heger 2007), elevating their bodies up off of hot surfaces to increase convection to cool breezes (Heger and Heger 2007), resting atop cool, moist substrates (Auffenberg 1994), retreating to burrows and other refugia (Warburg 1965a; Auffenberg 1981, 1994; Christian and Weavers 1996), and gular pumping (Johnson 1972; Owerkowicz et al. 1999). Some species, particularly those inhabiting arid environments with limited vegetation and cover can be heavily reliant on burrows for regulating and lowering body temperature; for example, studies on the ecology of *V. gouldii* have shown that temperatures inside burrows can be more than 18°C (32.4°F) cooler than aboveground conditions (Warburg 1965a).

THERMAL HUSBANDRY OF *VARANUS*

Successful herpetological husbandry demands that the biological requirements of a species are met, and that the environmental conditions provided in captivity replicate, as closely as possible, those available and familiar to a species in nature (Arena and Warwick 1995; Guillette et al. 1995; Lillywhite and Gatten 1995). Although some reptile species may do well in captivity when provided with minimalistic or "reductionist" husbandry conditions, such conditions are probably inappropriate for most species as they offer less potential to fulfil biological needs (Warwick and Steedman 1995). Given what is known about the ecology and thermal biology of free-living varanid lizards, it is clear that captive specimens require a broad range of temperatures and humidity levels that can be selected as needed to satisfy various physiological needs. However, multiple lines of evidence from the literature suggest that historically, varanids as a whole have not been provided with sufficient thermal conditions in captivity.

From a health perspective, several diseases and complications observed in captive varanids can be linked to inadequate thermal husbandry. Obesity, which is often attributed to excessively rich captive diets in reptiles (Donoghue and Langenberg 1996; Brown 2012), is common among varanid lizards (Boyer and Boyer 1997; Bennett 1998; Bennett and Thakoordyal 2003), but may have deeper roots in chronic exposure to low temperatures (Anonymous 1997, 1998a; Good 1999; Vincent and Wilson 1999; Lemm 2001; Bennett and Thakoordyal 2003). Under conditions in which eating is possible but activity levels and metabolisms are impaired by cooler temperatures, energy from food may be stored as fat, rather than allocated towards growth or reproduction (Bennett and Thakoordyal 2003), and several authors have argued that captive varanids, especially younger individuals, rarely become obese when provided with an appropriate range of temperatures to facilitate efficient digestion, even when offered large quantities of food (Anonymous 1997, 1998a; Retes, in Good 1999; Bennett and Thakoordyal 2003). Although empirical studies are lacking, chronic exposure to inadequate temperatures is also suspected of being etiologically linked to common metabolic disorders of captive varanids such as gout (Mendyk et al. 2013), weakened immune systems (Mendyk et al. 2013), and gastrointestinal diseases (Bacon 1976; Brown 2012).

From an ethological standpoint, captive varanids have rarely exhibited the same levels of activity as their wild counterparts, and their overall behavior in captivity has been described as lethargic by several authors. For instance, Barbour (1943) and Marcellini (quoted in Cohn 1994) both characterized varanids as "phlegmatic" in captivity, and Oliver and Spencook (1956) likened two *V. komodoensis* at the Bronx Zoo to "lethargic dogs". Murphy (1969) remarked that few captives exhibited the "characteristic alertness and activity associated with wild specimens", and that their lethargy was "depressing even to the casual zoo visitor". More recently, Gupta (1997) reported that captive *V. bengalensis* spent an average of 68.2% of their activity period basking, and Walsh et al. (1999) recognized that captive *V. komodoensis* "did not become completely inactive", but never exhibited the foraging activity levels characteristic of wild individuals. Descriptors such as these contradict what has generally been observed in, and reported for wild varanid lizards, which tend to be highly alert and active by nature, with several species known to travel expansive distances each day (Stebbins and Barwick 1968; Auffenberg 1981; Pianka 1994b). While spatial constraints and associated boredom may play some contributing roles in the behavior of captive varanids,

lethargy and prolonged basking activity are largely symptomatic of animals experiencing difficulties achieving and maintaining preferred body temperatures (Arena and Warwick 1995).

Despite signs of inadequate thermal husbandry being present in captive collections for decades, there appears to have been little concern or inquiry into why captives behaved markedly different than their wild counterparts, and even less testing and experimentation with the actual thermal preferences and tolerances of specimens in captivity. Surprisingly, many published accounts describing varanid husbandry over the past several decades have not included the specific basking temperatures (Moehn 1984; Sprackland 1989, 2007; Chippendale 1991; Kok 1995; Card 1996; De Lisle 1996; Mehaffey and McGinnity 1996; Wick 1996; Bayless and Dwyer 1997; Kala 1998; McDonald 1999; Hairston-Adams and Reed 2000; Dwyer and Bayless 2001; Eidenmüller 2005; Ryman 2009) or thermal gradients (Moehn 1984; Kala 1998; Eidenmüller 2005, 2007) offered to, or recommended for captives. This general lack of attention or concern for specific basking temperatures and thermal gradients suggests that thermal husbandry has largely been overlooked as an important component of varanid husbandry, especially when compared to other frequently discussed keeping parameters such as enclosure dimensions, diets, lighting, and photoperiod.

Earlier husbandry accounts that have cited specific temperatures often described or recommended surface basking temperatures of 35–40°C (95–104° F) and below (Murphy 1969, 1971, 1972; Behrmann 1981; Barker 1984; Erdfelder 1984; Davis et al. 1986; Radford and Paine 1989; Thissen 1993; Card 1995; Fost 1996; Holmstrom 1996; O'Dell 1996; Strimple 1996; Hartdegen 1998; Kirschner 1999; Gorman 2000; Lee 2000; Lee and Friedman 2000; Grützner 2003). Considering that the preferred active body temperatures of most wild varanid lizards appear to exceed 35°C (95°F), and that active body temperatures over 40°C (104°F) are not uncommon in free-ranging individuals (Auffenberg 1981,1994; King et al. 1989; King and Green 1999; Thompson et al. 1999), surface basking temperatures of 40°C (104°F) and below may prohibit captives from reaching their preferred body temperatures, or prevent them from doing so within a reasonable timeframe. These values also contradict the surface temperatures generally experienced and utilized by varanids under natural conditions, which frequently exceed 50°C (122°F) (Auffenberg 1981, 1994; Christian and Bedford 1996; Christian and Weavers 1996; Jackson 2005; J. Lemm, unpub. dat., D. Kirshner, pers. comm.; Fig. 1). In some published accounts where thermal gradients have been discussed, ranges of less than 10°C (18°F) have been reported (Barker 1984; Zimmermann 1986; Radford and Paine 1989; Sprackland 1989; Card 1995; Kok 1995; Bayless and Dwyer 2001). Considering the heterogeneity of climatic and physical conditions present in wild varanid habitats (Warburg 1965a; Auffenberg 1981, 1988), such limited thermal gradients in captivity may not provide individuals with an appropriate range of temperatures to thermoregulate effectively or efficiently.

A Paradigm Shift.—Beginning in the mid-1990s, a novel approach to the thermal husbandry of varanid lizards began to emerge from the private keeping sector in North America, which focused more on the ecology and thermal biology of free-ranging animals than previous methodologies. American herpetoculturist Frank Retes is credited with pioneering and promoting the use of elevated surface basking temperatures which had not previously been used or considered for varanids (Anonymous 1997, 1998a; Good 1999; Retes and Bennett 2001), perhaps due to fears that they would prove lethal to captives. Retes showed that when given access to a broad range of temperatures, captive individuals of many different varanid species selected surface temperatures in excess of 60°C (140°F) for basking. These elevated basking temperatures reduced the amount of time needed for captives to reach their preferred body temperatures, and led to greater activity levels and faster rates of digestion, growth, and sexual maturation (Anonymous 1997; Retes and Bennett 2001). Additionally, these conditions, in conjunction with the offering of small, but frequent meals have been attributed to marked increases in Retes' captive breeding success not just with diminutive species belonging to the subgenus *Odatria* (Anonymous 1997, 1998a,b; Good 1999;

Retes and Bennett 2001), but larger species such as *V. varius* and *V. albigularis* as well (Anonymous 1998a; F. Retes, pers. comm.).

Captive breeding success with varanids had been experienced by zoos and private keepers prior to this innovation (see Horn and Visser 1989, 1997); however, most occurrences before the mid- to late-1990s were infrequent, and rarely repeated. When adopted, the use of elevated basking temperatures and broader thermal gradients has led to greater activity levels and reproductive success with many species in both zoos and private collections, including multiple captive-bred generations (Fyfe et al. 1999; Good 1999; Bennett 2001; Retes and Bennett 2001; Bennett and Thakoordyal 2003; Husband and Bonnett 2009). For example, Fyfe et al. (1999) reported that a group of *V. brevicauda* initially provided with a basking spot of 35°C (95°F) remained inactive, had poor appetites, and did not engage in any courtship or mating behaviors. Upon increasing the surface basking temperature to 45°C (113°F) following Retes' methodology, activity levels and appetites increased, and courtship was observed within just a few weeks (Fyfe et al. 1999). Today, surface basking temperatures as high as 60°C (140°F) are offered to *V. brevicauda* in captivity (Husband and Bonnett 2009), and similarly high basking temperatures are successfully used for many other varanid species as well (Tables 1 and 2; Fig. 2). Even species with lower preferred body temperatures such as *V. mertensi* and *V. salvator*, and dense-canopied forest dwellers such as *V. prasinus*, *V. rudicollis*, *V. dumerilii*, and *V. olivaceus* will actively seek out and bask at these elevated temperatures when given the option to do so (Fig. 2).

Surface basking temperatures in excess of 45°C (113°F) have been in use with captive varanids and extensively documented in the literature for more than a decade (Visser 1985; Anonymous 1997; Good 1999; Husband and Vincent 1999; Retes and Bennett 2001; Bennett and Thakoordyal 2003). Yet, it appears that many zoos and private keepers are unfamiliar with this innovation or are perhaps following older husbandry guidelines, and several authors have recently reported or recommended the use of substantially cooler basking temperatures and narrower thermal gradients (Downing 2007; Gaikhorst et al. 2010; Donovan 2012; Purser 2014). Preliminary investigations on the thermal husbandry offered to varanids in captivity have also shown that some North American zoos are currently offering surface basking temperatures as low as 25–30°C (77–86°F) (Mendyk et al., unpub. dat.), which are substantially lower than the actual preferred body temperatures of most species. This may be reflective of information presented within outdated taxon management accounts that are still in use today which recommend surface basking temperatures below 45°C (113°F) (Pfaff and Sprackland 1996) or do not recommend any specific basking temperatures at all (Card 1996; Mehaffey and McGinnity 1996; Hairston-Adams and Reed 2000). Moreover, these findings might also reflect a general unfamiliarity with current literature on the biology and husbandry of varanids as well as limited communication between zoos and private keepers. Zoos and private keepers that follow outdated information may be providing inappropriate husbandry that can directly affect the health, welfare and longevity of captive specimens.

Now widely practiced throughout many North American, Australian, and European collections, the use of elevated basking temperatures above 45°C (113°F) does not appear to have been as extensively adopted by zoos and private keepers in Germany, where lower surface basking temperatures continue to be used for many species (Moldovan 2007, 2008; Wesiak 2007, 2008; Berghof 2009; Ziegler et al. 2009, 2010; Mendyk et al., unpub. dat.). While this trend does appear to be changing (e.g., Fischer, 2012; Hörenberg 2013a,b; Ramm 2013a,b; Mendyk et al. unpub. dat.), this more traditional keeping approach may be popular because several pioneering varanid keepers in Germany have reported breeding success with lower basking temperatures and narrower thermal gradients (Stirnberg and Horn 1981; Eidenmüller and Horn 1985; Eidenmüller 1990; Eidenmüller and Wicker 1991,1993; Horn 1991; Kirschner 1999). Although successful reproduction may occur under such thermal conditions, consistent and repeated reproductive success, multi-clutching, and earlier sexual maturation appear to be rare. The elevated basking temperatures and broad thermal gradients highlighted in this, and other reports (see Tables 1 and 2) offer many biological benefits over these more traditional keeping methodologies, and more closely mirror the range of climatic conditions present and familiar to varanids in nature.

Biological Benefits of Elevated Basking Temperatures

When unable to achieve their preferred body temperature, varanids may exhibit reductions in food intake, digestive efficiency and energy conversion, thyroid activity, and growth rates (de Grijis 1899; Buffenstein and Louw 1982; Fyfe et al. 1999; Brown 2012). Whereas elevated body temperatures accelerate enzymatic and mechanical digestive functions in reptiles (Auffenberg 1981), colder temperatures impair digestive abilities (de Grijis 1899). Low temperatures can lead to the putrefaction of food within the gut (Auffenberg 1981) as well as gastrointestinal impactions (Brown 2012), and have also been implicated in two fatal cases of severe gastroenteritis in *V. komodoensis* (Bacon 1976). When given access to broad thermal gradients including elevated basking temperatures, captives exhibit increased activity levels, greater appetites, faster growth rates and earlier sexual maturation, as well as improved reproductive outputs (Fyfe et al. 1999; Retes and Bennett 2001).

Access to a broad range of temperatures can also benefit reproductively active females. For instance, Kuhn and Julander (1999) noted that female *V. acanthurus* bask extensively at higher surface temperatures (to 71°C [159.8°F]) when gravid. Given the histories of low egg viability in captive varanid lizards (Mendyk 2012, unpub. dat.) and inadequate thermal husbandry, it is possible that access to higher temperatures may be important for healthy egg development, as well as normal reproductive cycling (i.e., oogenesis, vitellogenesis and ovulation). Inadequate thermal conditions may also explain, to some extent, the high frequency of reproductive complications and disorders seen among captive females (Mendyk et al. 2013).

Gout, the accumulation of uric acid crystals in the joints and viscera, is a common metabolic disease of reptiles in captivity. Although comparative studies with other reptile groups are lacking, captive varanid lizards have shown a particular susceptibility to gout (Köhler 1992; Hartdegen 2002; Mendyk et al. 2013). Exposure to cold temperatures can inhibit renal tubular function and increase uric acid levels in reptiles (Hernandez and Coulson 1957), and may explain elevated levels of uric acid seen in *V. griseus* during brumation (Haggag et al. 1966; Dessauer 1970) as well as cases of gout in captive varanids, although chronic dehydration has also been proposed as an important causative agent of the disease (Card 1996; Yuyek 2012; Mendyk et al. 2013).

Immunocompromised reptiles often elevate their body temperatures beyond their preferred Tbs, when ill (Kluger

1979; Warwick 1991; Hutchinson and Dupre 1992; Lillywhite and Gatten 1995). Similar observations of wild-caught varanids in captivity suggest that captives select higher basking temperatures for eliminating parasite loads (Sprackland 1989; Mendyk, pers. observ.), perhaps by increasing body temperature beyond the critical thermal maximum of the infective agent. There is also evidence that suggests reptiles purposely seek out colder temperatures during certain stages of illness, perhaps as a way to cope with stress associated with disease (Warwick 1991). Therefore, providing access to a broad thermal matrix including cooler temperatures and elevated basking spots that animals can actively select from as needed is important for facilitating a healthy immune response.

Health Concerns Associated with Elevated Basking Temperatures

Without testing the thermal preferences and tolerances of captive specimens under one's care, it is easy to see why some zoos and private varanid keepers may be reluctant to provide surface basking temperatures in excess of 45°C (113°F), for fear that death or thermal burns might occur (Retes, in Good 1999). Although some varanid groups and species appear to seek out greater surface basking temperatures than others, particularly members of the subgenus *Odatria* (Table 1), if surface basking temperatures are too hot, animals will usually bask at the site's periphery where temperatures are slightly lower. Most burns in captive varanids appear to be related to animals coming into

Table 1. Elevated surface basking temperatures and broad thermal gradients documented in the literature for varanid lizards belonging to the subgenus *Odatria*. direct physical contact with heating elements or protective wire cages surrounding heating elements (Horn and Schurer 1978; Greek 2010; Brown 2012), rather than the heated surfaces themselves. Burns arising through contact with extreme surface temperatures, although rare, may be possible only in certain circumstances where cold lizards maintained under cold ambient conditions are exposed to concentrated hot spots that cover too little an area of an animal's body (Good 1999; Vincent and Wilson 1999; Husband and Bonnett 2008; Brown 2012). An animal's body size should therefore dictate the size and coverage of basking areas, and for larger species, clusters or rows of multiple heating elements, as opposed to just a single fixture, have successfully been used to generate evenly distributed, elevated basking spots which provide entire body coverage (Good 1999; Bennett and Thakoordyal 2003; Kirshner 2007; Burokas 2012). Another potential concern is that some halogen flood lamps feature a clear lens in the center of the bulb which can direct a concentrated, magnified beam of light on a relatively small focal point, and are best avoided as heating fixtures.

Concerns of captives overheating can be dismissed, provided that access to a sufficiently broad range of temperatures is available (see below). A growing trend among private varanid keepers, which seeks to further replicate the conditions familiar to many species in nature, is the use of deep (sometimes up to 1 m), naturally-occurring substrates such as soil, sand, and loam which facilitate burrowing. Deep burrows and similar refuge sites can provide relief from warmer ambient air temperatures, and greatly increase thermal variation within an enclosure. Some zoos, however, may be unable, or reluctant to provide deep substrates for burrowing species, as burrows can interfere with the observation of specimens maintained on public display. In such circumstances, providing cooler refugia may require novel and innovative approaches which take into consideration the ecology and biological requirements of the species as well as display values. Similarly, since most private keepers are unable to accommodate spacious enclosures in their households, creating broad thermal gradients in diminutively sized enclosures presents its own set of logistical challenges, but is possible with careful planning and design.

The relationship between temperature and humidity is often overlooked in herpetological husbandry, even though it is widely established that water loss in reptiles is strongly influenced by both of these environmental factors (Warburg 1965b; Cohen 1975; Thomspon and Withers 1997; DeNardo et al. 2004). Enclosures with liberal screen or wire mesh coverage, and warmer than room temperatures (especially those used for basking) can create a significant air-flow, leading to a loss of humidity, and ultimately drier ambient conditions within the enclosure. Without access to high humidity levels, animals lose water to the captive environment through cutaneous evaporation and respiration, which can lead to dehydration, related health complications, and death. Reducing the amount of ventilation and incorporating deep, moisture-retaining natural substrates can help maintain appropriate ambient humidity levels within enclosures (Mendyk et al. 2013), provided that drainage and airflow are adequate for preventing microbial growth and associated health issues. Moreover, providing a variety of refuge sites with varying levels of humidity that captives can select from as needed further replicates the variation in microhabitats and microclimates experienced in nature, and can help further reduce the risk and health consequences of dehydration.

Implications for Biological Research

Ex situ investigations are frequently used by herpetologists to study various aspects of reptilian biology, particularly biological parameters that may not be possible or logistically feasible to study in the field. Although short-term laboratory investigations typically do not require the longevity that keeping reptiles in zoos and private collections does, biologically appropriate husbandry practices are still necessary for maintaining healthy research subjects. Captive varanid lizards have served as important study subjects in numerous investigations on reptilian physiology, psychology, and behavior (Bartholomew and Tucker 1964; Bennett 1972, 1973; Green 1972; Loop 1974, 1976; Berger and Heisler 1977; Meek 1978; Earll 1982; Cooper 1989a,b; Thompson and Withers 1992; Christian et al. 1996; Kaufman et al. 1996; Secor and Phillips 1997; Thompson 1997; Bennett et al. 2000; Frappell et al. 2002; Clemente et al. 2009; Gaalema 2011; Schachner et al. 2014). The fact that basking temperatures and thermal gradients offered to varanids in captivity have historically been inadequate could have far-reaching consequences which cross over into biological research. Captive conditions that prevent or discourage animals from reaching their preferred body temperatures can have direct effects on their activity levels, behavior, and performance (Christian and Weavers 1996). As a result, thermally compromised individuals may not be operating under optimal physiological conditions, which can skew experimental results and their interpretations.

One particular study, in which thermal husbandry practices may have had an unintended effect on its results and interpretations, compared the active body temperatures of captive *V. komodoensis* to free-ranging wild individuals (Walsh et al. 1999). This study found that captive *V. komodoensis* maintained active body temperatures that were significantly cooler than those recorded from wild conspecifics. Two potentially feasible explanations were offered for these unusual results. The first suggested that captives may have chosen to operate at lower body temperatures because of the reduced energy demands of captivity created by confinement and food provisioning (Walsh et al. 1999). The other suggested that the lower body temperatures in captives may have been a physiological response to the smaller size of prey items and greater frequency at which they are fed when compared to the larger and less frequent meals typical of wild *V. komodoensis*, which might require higher temperatures for digestion (Walsh et al. 1999).

A possible alternative hypothesis, not discussed by Walsh et al. (1999), relates to the range of temperatures available to captives for thermoregulation. Since the 40°C (104°F) maximum surface basking temperature offered to captives in the study (Walsh et al. 1999) is substantially cooler than the surface temperatures individuals would normally have access to for basking in nature (Auffenberg 1981), heating rates among captives were probably slower than in free-living wild individuals. Considering the activity levels, foraging habits, and general inquisitiveness of varanid lizards, particularly *V. komodoensis* (Auffenberg 1981; Burghardt et al. 2002), it is possible that captives chose to forgo reaching their optimal Tbs for other activities simply because it was taking too long to heat up. Field studies on seasonal body temperature variation in varanid lizards have reported similar findings, where several species maintain year-round activity, but operate at lower body temperatures than their optimal range during colder weather (Auffenberg 1994; Christian and Weavers 1996; King and Green 1999; Ibrahim 2000; Rathnayake

et al. 2003). King and Green (1999) showed that wild *V. rosenbergi* spent nearly three times as much time basking to elevate Tbs during colder winter months than in summer, yet never achieved the same active Tbs as in summer (29.3 vs 32.0°C [84.7 vs 89.6°F], respectively). The inability to reach optimal Tbs, or an inability to reach them within a reasonable timeframe would explain why varanids operate at lower Tbs during colder weather, and may explain a similar phenomenon in captive *V. komodoensis*.

Another important consideration is that as heliotherms, varanids largely rely on heat generated by the sun, a visible heat source, for elevating their body temperatures and typically thermoregulate by moving between sunlit and covered areas. Although empirical studies have yet to compare the thermoregulatory behaviors of varanids when given a choice between visible (i.e., natural sunlight, mercury vapor lamps, incandescent lamps, etc.) and non-visible (i.e. infrared heat emitters) heat sources for basking, observations from captivity suggest that at least some species respond differently to basking sites generated by different wavelengths of light (Laszlo 1969; Vincent and Wilson 1999; Deutscher 2006). For instance, when given access to both a non-heat emitting fluorescent coil lamp and a heat-producing halogen flood lamp, two *V. similis* repeatedly sought out and basked for extended periods under the fluorescent lamp, even though it did not emit any heat (Mendyk, unpub. obs.). Similar observations of basking behavior have also been reported for *V. timorensis* when given access to full-spectrum fluorescent lighting (Laszlo 1969). The infrared quartz heaters used by Walsh et al. (1999) to create a basking site for their *V. komodoensis* generated heat without producing visible light, and may have had some unintended effect on basking behavior. Several authors have suggested that captive varanids may not receive the same behavioral cues from non-visible, light-emitting heat sources as they do when basking under a visible light source (Card 1995; Vincent and Wilson 1999; Eidenmüller 2005), and while Walsh et al. (1999) noted that *V. komodoensis* occasionally entered the basking spot during the study period, it is possible that the animals may have been more drawn to basking in natural sunlight filtered through the exhibit's extensive skylights and windows than under the heater itself, which could have also had an effect on selected body temperatures. The tendency of diurnal reptiles to seek out filtered natural sunlight over infrared heat for basking has been observed in other species in captivity including *Astrochelys radiata* and *Phelsuma madagascariensis* (R.W.M. and L.A., pers. observ.), and warrants further investigation, especially since these types of behavioral observations can illustrate the taxon-specific appropriateness of different types of heating elements in herpetological husbandry.

Concluding Remarks

Since captive reptiles are often provided with narrow and inadequate temperature ranges that are based on human-estimated requirements (Arena and Warwick 1995), it is important for keepers to approach herpetological husbandry with an open mind and experimental methodology. By ignoring baseless long-term keeping traditions and "folklore husbandry" (Arbuckle 2013), and actually testing the preferences and tolerances of specimens under their care, keepers can develop and employ more effective biologically-appropriate husbandry practices. Based on our review of the thermal biology and captive maintenance of varanid lizards, several conclusions (see below) can be reached about their thermal husbandry. Applying this information towards current keeping methodologies can help zoos, private keepers, and research laboratories improve the welfare, keeping, and reproductive success of specimens in their care.

1) Surface basking temperatures below 45°C (113°F) and narrow thermal gradients may prohibit animals from reaching their preferred Tbs or prevent them from achieving them within a reasonable timeframe.

2) Broad thermal gradients which extend from 22°C (71.6°F) to elevated basking temperatures in excess of 45°C (113°F) (sometimes as high as 70°C [158°F] for some species) allow captives to select from a wide range of temperatures as needed to satisfy various physiological requirements, and offer many biological benefits over older, traditional keeping methodologies.

3) Access to a range of elevated humidity levels, including those near or at the point of saturation is important for captives to reduce and control evaporative water loss to their environment, and prevent dehydration.

4) Biological research carried out in captivity should consider the ecology and thermal biology of varanids when developing keeping methodologies to ensure that study subjects are provided with climatic conditions that allow them to reach their preferred Tbs and operate under optimal physiological condition.

Finally, in addition to establishing a target set of parameters for zoos, private keepers, and research laboratories to follow and incorporate into existing captive management practices, this study raises many additional questions relating to the thermal biology and thermal husbandry of varanid lizards. For instance, when provided with an unlimited range of basking temperatures, what is the highest temperature that a particular species will select for basking, and do these preferences vary with sex, age, or body size? How does basking behavior and the temperatures selected for basking differ under different ambient humidity levels, and is there a single, optimal body temperature for an individual, or do individual thermal preferences vary with age, reproductive state, physical condition, or season? These questions and others can be answered through carefully designed, captivity-based experiments, and represent a possible avenue for zoos and related facilities to contribute to research.

Acknowledgments.—We thank David Kirshner and Jeff Lemm for sharing unpublished data and observations, and Andrew Llewellyn, Bruno Mendes Gonçalves Ville, Steve Labib, Philip Glancy, David Kirshner, and the Smithsonian National Zoological Park's Department of Herpetology for contributing photographs. Brett Baldwin, George Sunter, and Ben Aller provided useful literature. We are also appreciative of early discussions with Frank Indiviglio which highlighted the necessity for this article. Lastly, we thank James B. Murphy for his continued support and feedback, and Daniel Bennett and two anonymous reviewers for constructive comments on earlier drafts of this manuscript.

As most sea turtle populations worldwide are declining, conservation efforts are focused on applying effective management plans to save these threatened populations. In order to rank management plans according to their potential benefit for species recovery and cost effectiveness, Heppell et al. (1996) developed models and predicted that small declines in annual survival rates of adult and sub adult Loggerheads (*Caretta caretta*) can have a profound impact on population dynamics. A loss of only a few hundred sub-adult and adult females each year could lead to extinction of a population in less than a century. Survival in the first year of life is relatively less important in these long-lived and slow-maturing animals (Heppell et al. 1996). Attempts to overcome the first year vulnerability by head starting projects have had controversial results (Frazer 1994; Heppell et al. 1996) Conservation measures must therefore prioritize the protection of the adult and last juvenile stages(RAC/SPA 2003).

Consequently, rescue centers are one of the most important tools in sea turtle conservation, elevating the population's survival rate by saving mature individuals struggling for survival against natural and anthropogenic threats and returning them to the wild to reproduce. Furthermore, the work carried out in these facilities helps raise marine conservation public awareness through tourism, media, educational programs and volunteerism, using sea turtles as flagship species.

During the last decade, new rescue centers have been established and developed around the globe. A sea turtle arriving at a rescue center often requires intensive handling and medical procedures. Although this process is extremely important for treating the turtle, it can be stressful for the turtle. We developed an intensive care tank to fit the specific needs of treatment, allowing procedures such as blood drawing, fluid and drug administration, force feeding, and hand feeding to be performed easily, greatly reducing the patient's stress, and elevating its chances of survival while allowing the caregiver accessibility in treatment.

The intensive care tank is ideal for treating sea turtles as well as other large aquatic chelonians (e.g., Nile Softshell Turtles, Alligator Snapping Turtles) on their first days of treatment. Assembly and operation are simple using the instructions presented here, and the low cost of materials enables even remote rescue centers to provide the best possible conditions for treatment of an injured sea turtle upon arrival.

Materials.—To create an intensive care tank unit for distressed sub-adult and adult sea turtles, conditions need to be optimized to reduce handling and stress while keeping the turtle

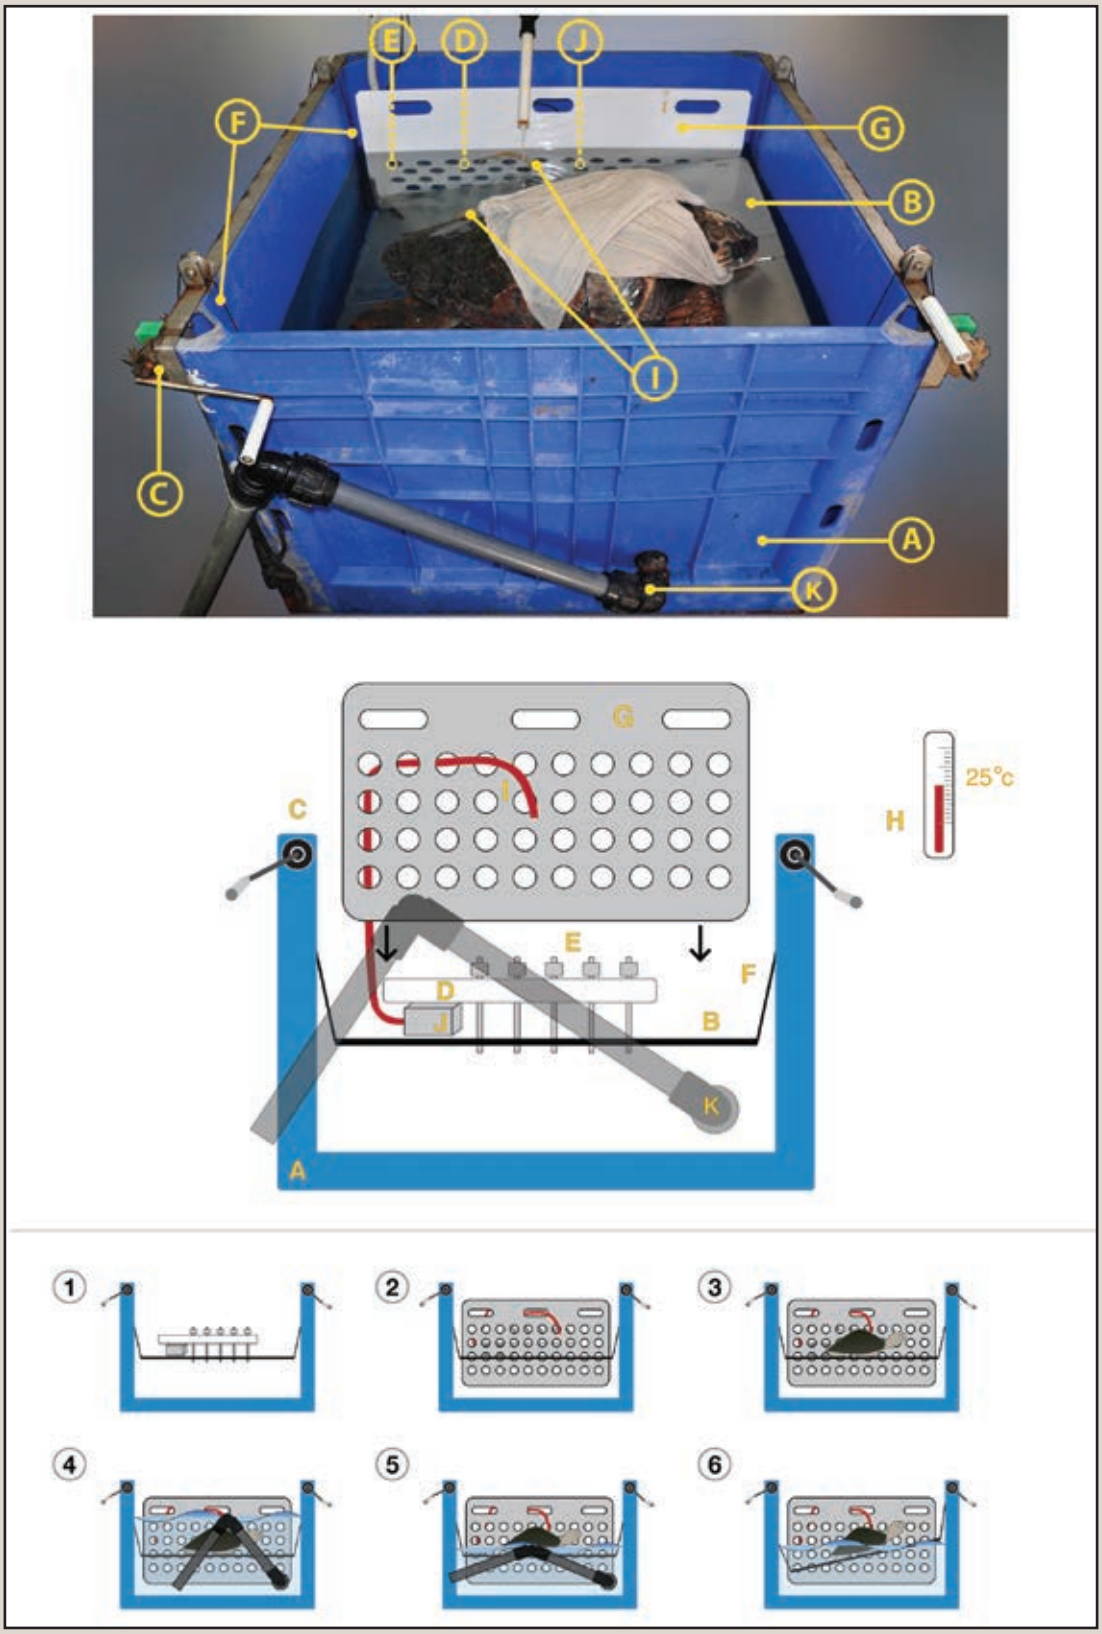

FIG. 1. Intensive care tank unit (ICTU). Detailed view of unit structure: (A–K materials explained in the text); I - ICTU temperature regulation; II - perspex plate separates the turtle from the heater and from entanglement in its electric wires while the warm water pipe extends out to the occupied area of the tank; III - turtle on the platform with warm water flow on its carapace; IV - external standpipe mounted to high water level; V - external standpipe mounted to low water level; VI - platform raised on one side.

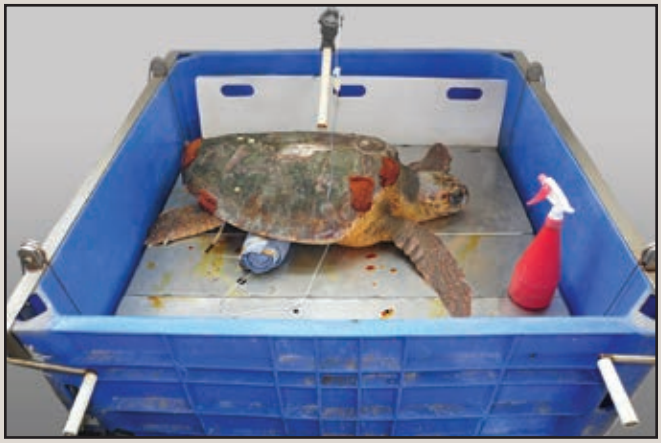

FIG. 2. A Loggerhead Sea Turtle treated with iodine and fluids in the ICTU using the treatment platform to hold it above water level, without taking the turtle out of the tank.

in a supportive environment of heated running sea water. The materials needed for the proposed unit are as follows: A) water tank with a volume of ~ 1 m³ (made of plastic/fiberglass, etc.) (110 cm × 110 cm × 80 cm); B) stainless steel treatment platform (90 cm × 100 cm); C) two axle handles and a sprocket mechanism; D) wooden plate; E) thermostat heaters (total capacity of 1,000—2,000 watts, e.g., five heaters of 300 watts each or three heaters of 500 watts); F) two stainless steel cables, 4 m each; G) polypropylene plate 1 x 0.6 m; H) thermometer; I) warm-water pipe; J) water pump; K) angled PVC standpipe (all shown in Fig. 1)

Mode of operation.—When first arriving at the rescue center, sea turtles are usually lethargic and hardly move. Movement can cause essential energy to be wasted, which can reduce treatment success. Therefore, the intensive care tank should be large enough to accommodate a mature sea turtle, but restrict its movement. A 1 m^3 tank is what we use in the Israeli Sea Turtle Rescue Center. Other rescue centers might need a larger tank to accommodate turtles representing larger individuals or species encountered in their region. Circulation and adjustment of the water level is done using an angled PVC standpipe (Fig. 1 K) exteriorly connected to the bottom of the tank wall, angled to the required water level (which can be different in each stage of the treatment), with its opening pointing to the drain. At the top of the angle, a hole is punctured in the pipe to avoid draining of the tank due to the connected vessels law of physics (Fig. 1; IV, V).

The best treatment conditions in severe and lethargic cases is to keep the turtle's head above water to prevent drowning, with most of the body mass in the water to decrease weight and pressure and to maintain the required temperature. The tank is therefore equipped with a treatment platform (Grade 316; Fig. 1B), connected to a simple sprocket mechanism, allowing it to be raised and tilted (Fig. 1; VI), with two separate axles, cables, and adjustable handles (Fig. 1F,C). By tilting the platform to the required angle, the turtle can be placed on top of it, with most of its body in the water, but the upper jaw is out of the water, protecting it from drowning. To keep the carapace wet and at appropriate temperature while the turtle is in this position, an internal water pump is used within a towel covering the carapace (Fig. 1J). The platform frame is made out of two separate units, allowing cleaning of the tank by removing each unit individually while the turtle is still in the tank. The platform can be used for other treatments which will be discussed later.

Water temperature.—Sea turtles are ectotherms and as such are dependent on externally derived heat to maintain enzymatic activity (Lawrence 1983). The immune response appears to be at a maximum when the turtle has a body temperature within its optimum thermal zone (Tait 1969; Cone and Marchalonis 1972; Jacobson and Origgi 2007). Therefore, the water temperature in the intensive care tank should be maintained between 25–30°C (Campbell 1996). Temperature is also an important factor in drug therapy. Higher temperatures may facilitate distribution of drugs within the body, thus achieving higher concentrations at the site of infection (Wilkinson 2008). Heating the water is also beneficial for treating stranded cold-stunned turtles. Sudden drops in temperature often result in hypothermia in sea turtles. In nature, cold-stunned turtles typically become weak, float, and strand (Paré and Jacobson 2007), or turtles may strand due to other health issues, and become hypothermic on a cold and windy beach.

The water in the tank is heated using thermostat heaters (Fig. 1E) with a total capacity of 1,000–2,000 watts depending on the influx and the temperature of the water entering the tank (Fig. 1; I). The heaters are submerged in the water through a floating wooden plate (Fig. 1D). The tops of the heaters (and the electric cables) are out of the water. To separate the turtle and the heaters, a polypropylene plate is placed vertically (Fig. 1G, II), dividing the tank into two unequal compartments; the smaller containing the heaters and the larger holding the turtle. Finally, a water pump circulates the heated water through the whole tank (Fig. 1J). Water supply should be adjusted to ensure the heaters are effective. If water flow is too fast, the heaters will not be able to keep the water warm enough. To ensure the heaters are effective, a thermostat is constantly regulating and displaying the water temperature (Fig. 1H). The power supply for the heaters is located in a dry place and when draining the tank (for cleaning) the heaters are unplugged and allowed to cool before taken out of the water.

Treatment options using the intensive care tank.—The intensive care tank was developed specifically to fit the needs of treating sea turtle injuries, and therefore can function in different ways to treat different cases. As pointed out above, the tank is equipped with a treatment platform allowing a variety of treatments by adjusting the position of the platform in the tank (Fig. 1; III, VI).

As a first step, the tank is filled with fresh water for rehydration and removal of marine organisms under a controlled temperature of 25–30°C (Campbell 1996). The turtle's buoyancy and breathing is carefully monitored during this period, and the water level should be adjusted accordingly. For example, in cases where the turtle cannot raise its head above water to inhale, the platform can be raised and tilted as described above, to prevent drowning (Fig. 1; IV, V).

After a while, the platform can be lowered again, so the turtle is submerged in water and continued to be monitored by the caregiver. If the platform is no longer necessary, it can be lowered to the bottom of the tank, or removed, while the turtle continues treatment in the intensive care tank.

In the case of nearly drowned turtles, on the first hours of arrival, in a dry tank, the platform is used to tilt the turtle's body downwards, so fluids can drain out of the respiratory system while the turtle is restrained to the platform. Tilting the turtle can also be useful while drawing blood. An angle of 30° is optimal for blood drawing (Owens 1999) and this can also be achieved using the platform, without taking the turtle out of the tank, reducing the stress involved in medical treatments.

When force feeding is required, the platform can be tilted so that the turtle is in an inclined position to help facilitate passage of the feeding tube into the stomach. Following removal of the feeding tube, the turtle is kept in the inclined position with the head and neck extended, until it swallows (Campbell 1996). Hand feeding might be necessary when treating a convalescent turtle and is easily preformed in the intensive care tank due to its small size and adjustable water level.

Fluid and medication injections can be performed with less handling using the treatment platform. It is used to elevate the turtle above water level for medical supplementation and for intra-coelomic injections such as fluids. For that, a towel is placed laterally below the rear plastron of the turtle to elevate one side in order to slide the organs in the coelomic cavity away from the puncture and allow insertion of the needle (Fig. 2).

A sea turtle arriving at a rescue center requires handling associated with medical procedures. Although this is necessary for treating the turtle, it can result in stress. Use of the intensive care tank can dramatically reduce the amount of stress, given that for most treatments the turtle does not need to be handled out of the tank. We have used the intensive care tank for the past 15 years, and believe it has had a major impact on treatment success of endangered sea turtles.

Acknowledgments.—We thank all the sea turtle rescue center volunteers, veterinarians (Itzhak Aizenberg, Yael Grundland, and Roni King), and Israel National Nature and Parks Authority workers. We owe a special thanks to Gabi Gabbay and Ishay Tshuva, who helped in the creation of the unit and its technical support, Meir Paltiel, Gil Cohen, and Shai Zagury, and to the Ministry of Environmental Protection and to the National Nature and Parks Authority for their support.

HERPETOCULTURE NOTES

SQUAMATA — LIZARDS

***PHRYNOSOMA ASIO* (Giant Horned Lizard). CAPTIVE DIET.** *Phrynosoma* spp. are generally regarded as ant specialists, principally of the genus *Pogonomyrmex* (Pianka and Parker 1975. Copeia 1975[1]:141–162; Whitford and Bryant 1979. Ecology 60:686–694). However, some species are not restricted to an ant diet, being more opportunistic when they have access to a variety of food resources (Lemos-Espinal et al. 2004. Herpetol. Rev. 2:131).

On 29 August 2010, I presented a captive adult female *Phrynosoma asio* (95 mm SVL, 142 mm TL, mass 44 g) and an adult male *P. asio* (94 mm SVL, 147 mm TL, mass 47 g) with a variety of potential food items (ants, crickets, mealworms, and other lizards). The female showed more inclination and preference to feed on a large number of black garden ants (*Lasius niger*) of the various morphs (queen, drone, workers, and soldiers) accompanied by higher levels of activity and vigorous captures. The male also showed more interest in eating all four categories of ants, but appeared to prefer worker ants. During the feeding trials, both lizards also consumed crickets (*Acheta domestica*) and mealworms (*Tenebrio molitor*). However, subsequent trials suggested that, when offered frequently, the level of interest by the lizards toward crickets and mealworms appeared to diminish. Additionally, I introduced two hatchling *Sceloporus grammicus* into the enclosure with the *P. asio* in order to record possible interactions between the two species. Both *P. asio* displayed interest in the other lizards, evidently aroused by their movements, and the female *P. asio* pursued and consumed both of the hatchling *S. grammicus*.

This is the first documented case of a *Phrynosoma* consuming other lizards under captive conditions. With these observations, I suggest that *P. asio*, although it is considered an ant specialist, is an opportunistic generalist in its diet. This should be taken into consideration in order to facilitate their maintenance in captivity, and perhaps also with other species of *Phrynosoma*.

I thank Tania Raya García for support in caring for the individuals in captivity and thanks to Fernando Raya López for providing the food for the horned lizards.

***UMA RUFOPUNCTATA* (Yuman Fringe-toed Lizard). BEHAVIOR.** *Uma rufopunctata* is a medium-sized (up to ca. 120 mm snout–vent length) species native to sandy dune habitats in southwest Arizona, USA and northwest Sonora, Mexico (Brennan and Holycross 2006. A Field Guide to Amphibians and Reptiles in Arizona. Arizona Game and Fish Department, Phoenix, Arizona. 150 pp.; Turner and Rorabaugh 2009. *In* Jones and Lovich [eds.], Lizards of the American Southwest: a Photographic Field Guide, pp. 274–277. Rio Nuevo Publishers, Tucson, Arizona). *Uma* spp. possess a number of morphological adaptations for inhabiting loose, sandy habitats (Stebbins 1943. Am. Nat. 77:38–52; Stebbins 1985. A Field Guide to Western Reptiles and Amphibians. Houghton Mifflin Co., Boston Massachusetts. 336 pp.; Lemm 2006. Field Guide to Amphibians and Reptiles of the San Diego Region. University of California Press, Berkeley. 326 pp.). Documented behavioral observations of this species are scarce, and to our knowledge, agonistic behaviors have not been described.

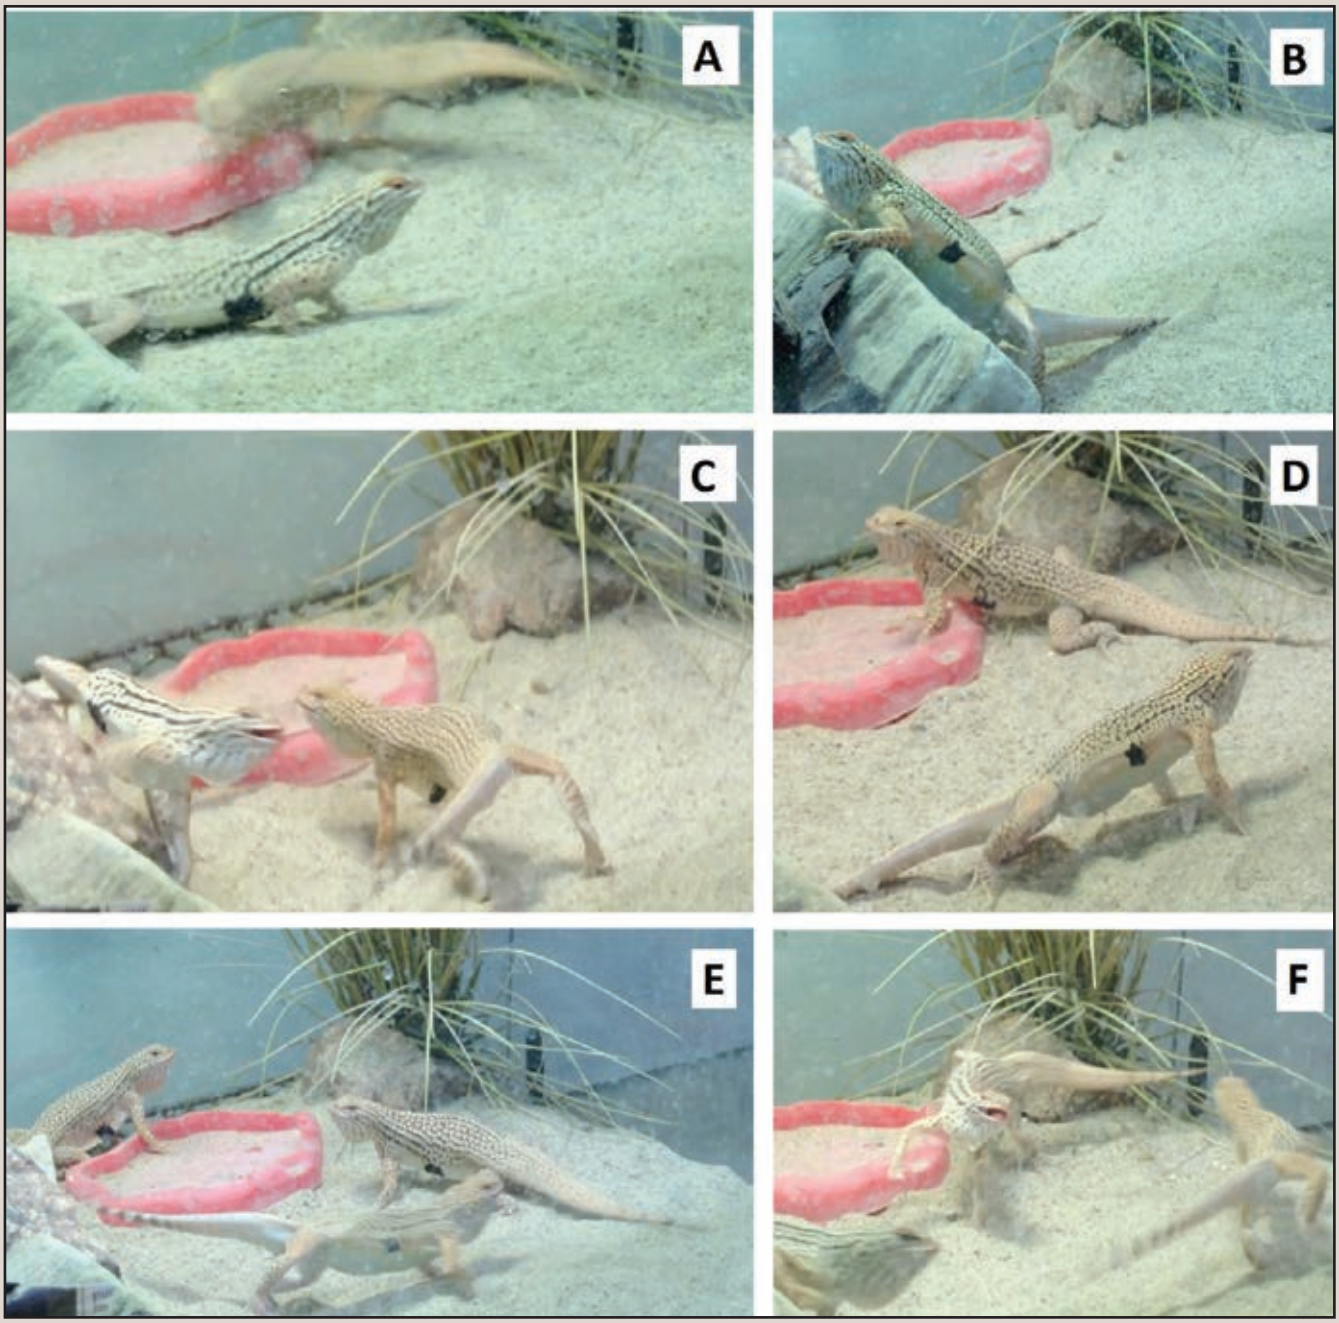

FIG. 1. Time series photographs from a video of agonistic behavior among three male Yuman Fringe-toed Lizards (*Uma rufopunctata*). Video recording began ca. 30 sec after aggression was first noted. A) Aggressor running at other male at 4 sec into the video. B) Male displaying inflated throat at 6 sec. C) Two males in combat; notice the inflated throat, open mouth and elevated and rotated body posture displaying the ventral stripe at 39 sec. D) Male at the top of a push-up at 43 sec. E) All three males displaying with inflated throats, ventral stripe and push-ups at 1 min 31 sec. F) Two males in an encircling combat with the ventral side of the body rotated towards the other combatant. A third male observes in the lower left corner of the picture at 3 min 46 sec.

The Phoenix Zoo received three male and four female (3.4) wild-caught *U. rufopunctata* from the Arizona Game and Fish Department on 12 June 2012. The animals were housed on public display in a group that always contained 2.3, while 1.1 were rotated to an off-display enclosure for breeding. Both breeding and exhibit enclosures were glass aquaria measuring ca. 91 × 46 × 43 cm with sand substrate and rocks for basking under an overhead Exo Terra® 160-watt Solar Glo UV/heat bulb. Temperatures ranged from 43°C on the sand surface under basking lights to 28°C on the cooler side of the enclosure. All animals appeared to cohabitate fine, with no noticeable aggression witnessed until the incident described below.

On 12 November 2013, animals were separated by sex; 0.4 were maintained in the display enclosure and 3.0 were moved into an off-display holding enclosure (also a 91 × 46 × 43 cm glass aquarium with a similar substrate and lighting/heating arrangement to that previously described). This was accomplished prior to cooling the animals over winter in an attempt to entice breeding the following spring. On the same day that the animals were separated, we observed the males in a combat ritual (Fig. 1). The episode started at 1330 h, ca. 4 h after moving the animals into the new enclosure, when two males, positioned approximately 15 cm from each other, began displaying towards one another with inflated throats and bodies while performing push-ups. Many lizard species perform push-ups to communicate with other individuals, displaying patterning/coloring of the ventral portion of their body and demonstrating physical condition, for species recognition, mate choice or attraction and territoriality (Carpenter 1965. *In* Milstead [ed.], Lizard Ecology: A Symposium, pp. 274–277, University of Missouri Press, Columbia; Ferguson 1971. Syst. Zool. 19:79–101). Push-ups were performed in a pattern of four quick push-ups using primarily their front legs followed by one slower and more exaggerated push-up using all four legs. This 4-1 pattern was repeated throughout the entire push-up routine for ca. 25 sec, at which time one participant ran towards the other. The two lizards elevated their ventral surface off of the substrate while rotating their dorsal surface towards and running in a circular motion around the other lizard. This elevated and rotated body posture also displayed the ventral side stripe to the other lizard. While in this motion, their throats were flared and mouths agape. This circling behavior occurred four separate times during the entire episode, with push-up behaviors, again in the 4-1 pattern, occurring between the active circling combat.

Just before the third circling combat, one of the males moved the distal 2-cm tip of its tail from side to side at ca. 10 undulations/sec for 1.5 sec. Caudal movements of squamates have been documented prior to prey capture (Heatwole and Davison 1976. Herpetologica 32:332–336; Murray et al. 1991. Copeia 1991:509–516; Mullin 1999. Great Basin Nat. 59:361–367; Foster and Martin 2008. West. N. Am. Nat. 68:257–259) and as defense mechanisms, be it tail autotomy (Arnold 1998. *In* Gans and Huey [eds.], Biology of the Reptilia, pp. 236–273. Alan R. Liss, Inc., New York) or rattling/vibrating (Greene 1973. J. Herpetol. 7:143–161). Additionally, tail lashing behavior has been documented in *Anolis* during male-male agonistic interactions (Ortiz and Jenssen 1982. Z. Tierpsychol. 60:227–238). The purpose of tail movements in this display could be as a potential distraction mechanism or simply a displacement activity (Tinbergen 1952. Q. Rev. Biol. 27:1–32).

The entirety of the event described lasted ca. 7 min. While the third male approached the two displaying males in the last three min of the event and exchanged push-ups and combat behavior, he remained outside the immediate area of the circling behavior of the two main combatants; remaining ca. 7 cm from the two displaying males. The Zoo now houses all sexually mature male *U. rufopunctata* separately.

Legislation and Conservation Efforts Concerning Crocodiles in Colombia: A Historical Review

The need to solve specific temporal and/or spatial-ecological problems framed much of the environmental legislation in Colombia before 1950 (Rodríguez 2009). Only after the first regional natural resource management agency was formed (C.V.C. in 1954) and the subsequent development of several national entities (Ministry of Agriculture 1957–1968, Institute for the Development of Renewable Natural Resources INDERENA founded in 1968 and in place until 1994), did Colombia started to have an integrative vision about its natural resources and the problems that a number of these resources faced. Following the Stockholm Convention in 1972, this country developed a renewable natural resources and environmental protection code (Law 2811 [1974]), which was the first comprehensive document that dealt with environmental legislation and management of natural resources. With the completion of a new national constitution (1991), and specifically with Law 99 (in 1993), Colombia established the Ministry of Environment as a regulatory and administrative agency, and also the National Environmental System (SINA). This administrative assembly generated tools that allowed structuring of an effective mechanism for the management and protection of environmental resources (Rodríguez 2009). At this time, fauna, flora, biodiversity, and ecosystems were topics framed as transverse lines in the Colombian legal framework. However, due to conflicts among civilian entities, industry, and supporters of conserving biodiversity that still exist in Colombia, in reality these comprehensive approaches are still not yet being practiced (Anonymous 2009).

Regarding members of the order Crocodylia, Colombia has the greatest diversity (along with Brazil) and is the largest producer of crocodilian skins in the world (Larriera et al. 2004). However, three of six Colombian crocodilian taxa are currently seriously threatened: (*Crocodylus acutus* [American Crocodile] and *Cr. intermedius* [Orinoco Crocodile] both catalogued as Critically Endangered; and *Melanosuchus niger* [Black Caiman] catalogued as Endangered; see Rodríguez 2002a,b; Rodríguez and Ramírez 2002). Another species—*Caiman crocodilus* (Spectacled Caiman)—has a fragmented distribution and depleted populations through its range (Barahona et al. 1996; Rodríguez 2000; Balaguera-Reina and González-Maya 2009). The aim of this study was to carry out a historical review of environmental legislation, conservation efforts, and program management of crocodilians in Colombia to determine their historical and current legislative status, their changes over time, and any projections about the future.

We conducted an extensive bibliographic search of the web databases of the Ministry of Environment as well as in archives of non-government organizations (NGOs) and research institutions. We recorded a total of 24 national resolutions, one decree, and two agreements between 1959 and 2011 (Table 1), with a maximum of three and an average of 0.51 ± 0.11 (SE) legislative actions per year. We also identified national conservation programs written for two crocodile species (*Cr. intermedius* [MMA 2002] and *Cr. acutus* [MAVDT and CVS 2005]), seven regional and local conservation programs (Maldonado and Ardila 2004; Ulloa-Delgado et al. 2005; De la Hoz et al. 2008; Medrano and Rojano 2008; Hernández-Rangel et al. 2010), and two management plans (Balaguera-Reina et al. 2008; Ulloa-Delgado 2011).

Historically, Colombia developed the first two resolutions about crocodilians between 1957 and 1968 (Acts 387 and 1023 of 1959); these focused on *Caiman sclerops fuscus* (current taxonomy, *Caiman crocodilus fuscus*) hunting regulations on the Magdalena River and its tributaries along the Caribbean coast. These resolutions also restricted live animal export except for permitted scientific purposes. Between 1968 and 1994, eight resolutions, one decree, and two agreements were released (Table 1) that focused on hunting bans on *Cr. acutus*, *Cr. intermedius*, *M. niger*, as well as on *Paleosuchus palpebrosus* (Cuvier's Dwarf Caiman) and *P. trigonatus* (Schneider's Smooth-fronted Caiman), and which regulated both scientific and farming collecting of these species. Finally, between 1999 and 2011, the Ministry of Environment published 14 resolutions concerned with developing management measures to regulate trade in two subspecies of *Ca. crocodilus* trade (*Ca. c. fuscus* and *Ca. c. crocodilus*), with the explicit goal of reducing poaching and illegal trafficking of these organisms.

Currently, five of the six Colombian crocodilian species are covered under a permanent hunting ban in all national territories: *Cr. acutus, Cr. intermedius,* and *M. niger*, Resolution

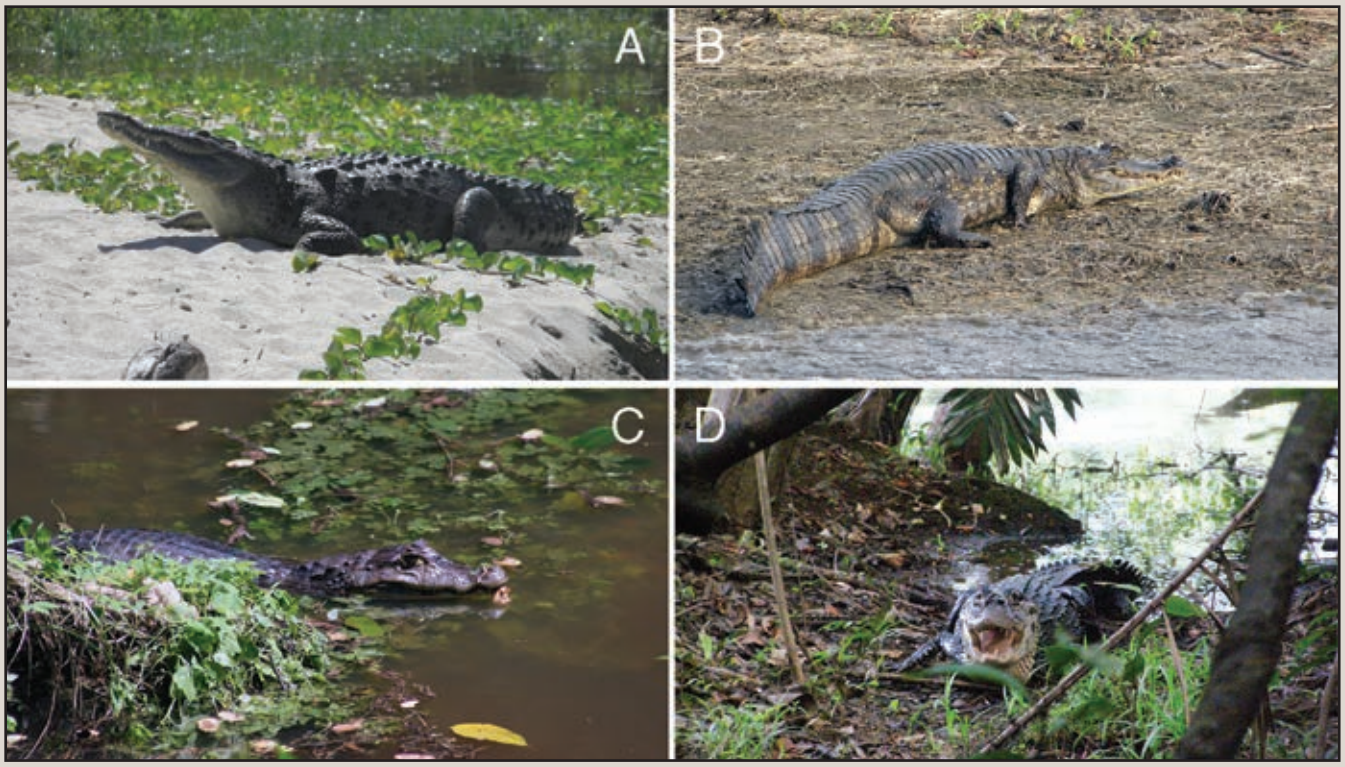

FIG. 1. Four taxa of Colombian crocodilians: A) *Crocodylus acutus* (American Crocodile); B) *Caiman crocodilus crocodilus* (Common or Spectacled Caiman); C) *Caiman crocodilus fuscus* (Brown Caiman); D) *Melanosuchus niger* (Black Caiman).

573 (1969); and *P. palpebrosus* and *P. trigonatus*, Resolution 530 (1970). Interestingly, *Ca. crocodilus* has not been covered under any direct resolution that would ban hunting; only two subspecies (*Ca. c. fuscus* and *Ca. c. apaporiensis*) have specific regulations dealing with this topic. One deals with populations living in the Magdalena River and some adjacent departments (Resolution 847 [1973], see Table 1). The other deals with *Ca. c. apaporiensis* across all of its range (Agreement 39 [1985]). The incorrect or imprecise use of taxonomic nomenclature in nationwide management resolutions or decrees (both at the species and subspecies levels) reduces the possibility to easily apply controls against threats to the conservation of those taxa. In the case of *Ca. crocodilus*, the uncertainty of the ranges of the various subspecies, the lack of general knowledge about the populations and their biology, and the lack of protection, regulation, and management for other subspecies (besides *Ca. c. fuscus* and *Ca. c. apaporiensis*) all serve to complicate this issue.

Farming regulations (Resolution 873 [1974], Decree 1608 [1978]) encouraged scientific studies for all the species (*Cr. acutus*, *Cr. intermedius*, *Ca. crocodilus*, *M. niger*, *P. palpebrosus*, and *P. trigonatus*) significantly increasing our knowledge about the reproductive ecology of some of these (Chiriví 1973; Medem 1981). Currently, while legal farming has been approved for *Cr. acutus*, *Cr. intermedius*, *M. niger*, and *Ca. crocodilus* (except *Ca. c. apaporiensis*; Agreement 39 [1985]), ironically, only *Ca. crocodilus* meets the international requirements necessary to allow it to be traded (*Cr. acutus*, *Cr. intermedius*, and *M. niger* are all Appendix I of CITES; CITES 2012). On the other hand, species such as *P. palpebrosus* and *P. trigonatus*, which currently do not have any recognized commercial value have received little interest from legislators or management programs.

At present, Colombian crocodile market depends exclusively on *Ca. crocodilus* farming (Larriera et al. 2004; Velasco and Ayarzagüena 2010). This activity stimulated the development of specific legislation about this species since farming was at least in part started to protect wild populations. However, large-scale poaching of this species is still occurring throughout the country (Balaguera-Reina et al. 2008). Since 1999, the government and farmers are working together to try to eradicate any skin trade derived from poaching (Resolution 154 [1999]) and to optimize conditions for long-term sustainable production. Actions such as the determination of quotas by the Ministry of the Environment disseminated as national resolutions (Resolutions 706 [2002] and 840 [2003]), forbid the exportation of products not verifiable by legal farming (Resolution 767 [2002]), and mark all legally recognized parental stocks in the country (Resolutions 1172 [2004] and 221 [2005]). Unfortunately, a substantial and unexplained increase (60%) in skin exports in 2006 (based on 2005 data) without a corresponding increase in farming activity (Resolution 1740 [2010]) indicates that poaching and the illegal skin trade remain a major problem. This resolution argued that illegal trade in the country might have been as high as twice the amount of legal skin production between 2005 and 2010. To remedy this situation, Colombia developed more restrictive control measures (Resolution 1740 [2010]) (e.g., shipment inspections, leather certificates, export inventories) in order to eliminate as much illegal activity as possible. The overall picture for *Ca. crocodilus* in Colombia is of concern due to the limited knowledge that we have about the natural history of this species in the wild, the lack of conservation programs throughout its range, and the historical fragmentation and depleted populations documented by several authors (Barahona et al. 1996; Rodríguez 2000, Balaguera-Reina et al. 2008).

TABLE 1. Environmental legislation developed on crocodiles by the Ministry of Agriculture (1957–1968), the Institute for the Development of Renewable Natural Resources (INDERENA) (1968–1994), and the Ministry of Environment (1999–2011) in Colombia.

Type	Year	Aim
Resolution 573	1969	Established hunting ban on Caimán aguja (*C. acutus*), Caimán llanero (*C. intermedius*), and Caimán negro (*M. niger*) in all territory where INDERENA has jurisdiction.
Resolution 530	1970	Established hunting ban and prohibited commercialization of products derived from Cachirre (*P. palpebrosus* and *P. trigonatus*) in all national territory.
Resolution 564	1970	Defined payment amounts for the restocking of wildlife used in and from INDERENA's faunal territories: Caimán aguja (*C. acutus*), Caimán negro (*M. niger*) $ 200 pesos per individual; Babilla (*C. crocodilus*), Cachirre (*P. palpebrosus* and *P. trigonatus*) $ 30 pesos per individual.
Resolution 2	1972	Modified resolutions 574 (1969), 564 (1970), 039 and 110 (1971) and other provisions: Babilla (*C. crocodilus*) $ 3 pesos per individual.
Resolution 847	1973	Established hunting ban on the subspecies *C. c. fuscus* (Babilla del Magdalena) during April–July of every year. 150 cm of total length is determinated as the hunting minimum size in January, February, March, August, September, October, November, and December of every year. Trade in undersized and live animals is prohibited. Hunting in the departments of Boyacá, Cundinamarca, Huila, Meta, Tolima, Arauca, Guainía, Vaupés, and Vichada is banned indefinitely.
Resolution 873	1974	Scientific hunting of some individuals of the Order Crocodylia is temporarily allowed in all territory where INDERENA has jurisdiction: Tulisio *C. c. chiapasius* or *C. s. chiapasius* 100 individuals; Babilla del Magdalena *C. c. fuscus* or *C. s. fuscus* 120 individuals; Caimán del Amazonas *C. c. crocodilus* or *Caiman s. sclerops* 120 individuals; Caimán negro *M. niger* 30 individuals; Cachirre *P. palpebrosus* and *P. trigonatus* 20 individuals of each.
Decree 1608	1978	Established the Renewable Natural Resources Code and the Environmental Protection National Code and Law 23 (1973) on wildlife.
Agreement 039 between Agriculture Ministry and INDERENA	1985	Established list of vertebrate wildlife that can be hunted by farming: Babilla *C. crocodilus* (except *C. c. apaporiensis*) and Caiman negro *M. niger*. These species cannot be hunted without a promotion-hunting license.
Resolution 242	1990	Authorized the sale of Caiman aguja (*C. acutus*) individuals certified as offspring of second generation and marked with a special code of INDERENA's faunal stations for farming within the national territory.
Resolution 552	1994	Authorized the incineration of wildlife products seized.
Agreement 355 between Agriculture Ministry and INDERENA	1994	Authorized the interchange and loan of Caiman aguja (*C. acutus*) parental stock and the regulation of its sale.
Resolution 154	1999	Established export quotas and set criteria for marketing of farmed species.
Resolution 706	2002	Established maximum quotas for *C. crocodilus* for 2001.
Resolution 767	2002	Banned the export of some products of *C. c. fuscus*.
Resolution 840	2003	Established maximum quotas for *C. c. fuscus* for 2002.
Resolution 1172	2004	Established an ex situ Wildlife National Identification and Registration System.
Resolution 221	2005	Modified the 3rd and 6th article of Resolution 1172 of 2004.
Resolution 892	2005	Adopted methodology to allocate the Remainder Exportation Quota by *C. c. fuscus* included in CITES appendices.
Resolution 1660	2005	Established procedure and methodology that Regional Environmental Agencies should take for annual calculation of *C. c. fuscus* and *C. c. crocodilus* individuals to be used by farming.

(*continued on next page*)

TABLE 1. Continued.

Type	Year	Aim
Resolution 2352	2006	Modified resolutions 1172 (2004) and 0221 (2005) on establishing time for marking of parental farming stock of *C. c. fuscus*.
Resolution 923	2007	Modified Resolution 1172 (2004).
Resolution 383	2010	Designated threatened wildlife species in the national territory.
Resolution 1772	2010	Established requirements for commercial sale of farmed animals listed under CITES I.

Regarding *Cr. acutus*, recent efforts to regulate its trade are underway. Resolution 1772 (2010) has encouraged farmers to genotype all the animals maintained in farms in order to have an identification tool and help avoid illegal practices. Moreover, recently Colombia proposed that the CITES commission change the status of *Cr. acutus* populations in Cispatá Bay, Córdoba Department, from Appendix I to Appendix II as a result of the successful outcomes obtained in its conservation program over the last 10 years (Cop16 prop. CITES 2013). However, the CITES commission verdict was that *national* efforts must be developed across the range of the species before any such changes can be made. The Commission focused on the need to determine the current conservation status of the entire species distribution in Colombia, thus allowing the generation of management plans and conservation programs at the national level.

Overall, most legislation concerning crocodilians in Colombia has been the result of case-by-case efforts to reduce both short- and medium-term illegal use of the resource, which has not been a very efficient way to develop nationwide sustainable management approaches. It will be necessary to develop a comprehensive framework, which includes research, population monitoring, and careful management as the basis to use crocodilians (as well as other wildlife) as a sustainable resource.

Species such as *Cr. intermedius* and *Cr. acutus* already have national conservation programs in place, some of which have yet to receive formal approval and in general, not many of the actions described in these programs are currently being enforced. To insure that these species recover, it will be necessary to develop strong political support that will result in governmental efforts that allow the restoration of crocodilian populations and the future regulation of their use. On the other hand, it is curious that *Ca. crocodilus*, the one crocodilian species that supports the entire Colombian skin market, does not yet have a national conservation and management program; this clearly demonstrates the disconnect among the government, the skin industry, and conservation efforts in Colombia.

After the national census (Barahona et al. 1996), which recorded low densities in the majority of crocodilian taxa inhabiting Colombia, there is still considerable research that must be completed regarding species' ranges, population ecology, and actual versus perceived threats before any serious national efforts to conserve and manage the species in Colombia can be undertaken. We did find coupling of some management and conservation activities in areas such as Córdoba, Guajira, Chocó, Antioquia, Amazonas, and Norte de Santander, several of which appear to be highly successful (e.g., Cispatá and Portete Bays), but at the national level such efforts to resolve the conservation status of all crocodilians remains a concern.

Alternatives, for example the inclusion of government-sponsored ranching in Colombia as a production method and the construction of comprehensive legislation might stimulate the conservation of crocodilians in local communities because of the added economic value (Larriera et al. 2004) and should bring new perspectives to sustainable management in the country.

America's Crocodile Kings With Notes on the Range, Temperature Tolerance, and Nesting of *Crocodylus acutus* in Southwest Florida

America has produced some renowned herpetologists, some of them directors and curators of zoological parks. Men like Archie Carr, Roger Conant, Lear Grimmer, Moody Lentz, Jim Oliver, and Marlin Perkins often visited the two Florida brothers, Bill and Lester Piper, and their wildlife establishment, the Everglades Wonder Gardens, during the last century. These biologists and zoo people highly respected the Pipers and considered the men friends. Bill Piper often guided them on collecting trips and they relied on the Pipers' expertise in Florida's diverse herpetofauna. To a man they were all awed by the Pipers' collection of *Crocodylus acutus*.

> "We present the Everglades Reptiles Gardens without any particular training in showmanship or exploitation. Years of actual experience and contact with wildlife have given us an intimate knowledge of their habitat that we wish to share with you. We have only a sincere desire to give the visitor a clear pictures of the thrilling life, dangers, intrigue and constant struggle for existence that goes on in the depths of the impenetrable and fascinating Everglades. Sincerely, Wilford and Lester Piper"
>
> —*From their brochure, circa 1945*

In the Florida we know today, facilities that cater to the ecotourism industry attract countless enthusiastic visitors. Some of these attractions are publicly owned, others privately. The former generally feature visitor interpretive centers and ancillary educational programs. The most flamboyant of the latter are family entertainment-based and are profit-driven private enterprises. The most notable of these have evolved into major exhibits and have reached empiric proportions. Disney World and Busch Gardens are two of Florida's major attractions drawing in many tourists and resident Floridians; however, in bygone times, before these mega-tourist destinations, educational messages about Florida's wildlife and natural systems were provided by a network of exhibits that were dubbed, and are remembered as, "roadside zoos."

For more than a century, Florida's major highway network was well endowed with these small, mostly wildlife-based exhibits. A few of them remain part of our landscape, while others have drifted off into oblivion. Few living memories can explain the virtues of these exhibits or speak of their former popularity. Those that originated in the 19th and 20th centuries and are yet part of modern Floridana include: St. Augustine Alligator Farm (established 1893), Gatorland (established 1949), Gatorama (established 1957), and until relatively recently Everglades Wonder Gardens (established 1936).

Fig. 1. Map of pertinent site locations in South Florida. Adapted from Google Earth.

The last of those listed above started out in Southwest Florida 78 years ago as Bonita Springs Reptile Gardens. Unlike those listed above, this attraction was not based solely on a large collection of American Alligators. In 1935, Wilford "Bill" Piper (1900–1989), a resident of Wyandotte, Michigan, partnered with Ensil Ross Allen (1908–1981), the famed rattlesnake exhibitionist who operated Ross Allen's Reptile Institute, part of the popular Silver Springs attraction complex near Ocala. Allen had opened his exhibit in 1929. Bill Piper had spent some of his youth in Florida, near Largo in Pinellas County, where he developed an interest in the state's wildlife. After a couple of hitches in the US Navy, during and just after World War I, Bill made a substantial fortune working as a busy bootlegger on the Detroit River, moving alcohol between Wyandotte and Windsor, Ontario, Canada, during Prohibition in the US. He survived an assassination attempt by a rival gang of rumrunners not long before Prohibition ended and he came back to Florida to hide, mend, and begin a new life. He and Ross Allen invested in a joint venture apart from the Reptile Institute and opened a "wildlife farm" operation about 40 miles east of Ocala. The partnership soon failed because of personal conflicts between the men after a joint herp-collecting trip to Honduras. Bill Piper moved on to settle in Bonita Springs, in Southwest Florida, where he partnered with his younger brother, Lester (1902–1992), who had helped him in the illicit liquor importation business. The pair started collecting local wildlife in 1936 and officially opened their Bonita Springs Reptile Gardens in 1938. Their attraction would evolve through two name changes. In the late 1930s it was called Everglades Reptile Gardens and by the late 1940s the business name had morphed to Everglades Wonder Gardens (EWG). The word "reptile" was dropped from their business name because the brothers thought that the word implied "snakes" to the more squeamish tourists who disliked ophidians and this was a factor that could cause them to lose revenue. This wildlife and botanical exhibit eventually became the premier privately operated wildlife attraction in Florida. By the early 1950s, the Piper brothers' collection of Florida wildlife was nationally renowned, envied by all of their competitors, and admired by directors and curators at major zoological parks nationwide.

PHOTO COURTESY OF ANNA PIPER MACKERETH

FIG. 3. Some of the adult crocodiles in the Piper collection in 1952. The person standing to the left outside the enclosure is Donald Carroll. He managed the Gardens from 1950 to 1955 until he left and took a position with the Florida Game and Freshwater Fish Commission. In October 1956, while Don was lecturing to a group of schoolchildren in Perry, Florida, he stepped on a loose fresh-caught and "hot" Eastern Diamond-backed Rattlesnake (*Crotalus adamanteus*) to prevent it from dropping off the stage and reaching the children. In an unusual move the rattler slung more than half of its body around and struck Don behind and above his left knee, in his lower thigh, just above the top of his new Gokey snake-proof boots. Despite all efforts at the Tallahassee hospital Don died 22 hours after the bite. Note the male crocodile in the left foreground. Its mouth was tied shut until the individual's aggressive sexual/territorial behavior waned.

Not satisfied with just displaying snakes and alligators to educate and fascinate travelers who stopped and paid their modest entry fee, the brothers expanded the scope of their wildlife presentation. With species diversity as their goal, in 1936 the Piper brothers began to collect a variety of native wildlife including alligators, showy birds, large mammals, and American Crocodiles (*Crocodylus acutus*). Their collection of *C. acutus* would later be advertised as "the world's largest collection of Florida crocodiles in captivity"—and it was. The majority of these crocodilians came from the mangrove forests of upper Florida Bay.

Crocodylus acutus in Southwest Florida

The modern distribution of the American Crocodile in Florida is well described by Kushlan and Mazzotti (1989). Mazzotti (1999) suggests that in the modern era *Crocodylus acutus* has dispersed from its historic range in upper Florida Bay and has moved west to Cape Sable. Today the American Crocodile periodically nests successfully on East Cape (Cape Sable, Everglades National Park) and their nest sites are frequently found in that vicinity (K. Morrison, pers. comm.). Actually this species ranges in growing numbers beyond this southernmost mainland section of the Florida peninsula. Since 1936 individuals of *C. acutus* have historically ranged north through the Ten Thousand Islands into Southwest Florida (LeBuff 1957; LeBuff and Lechowicz 2013). Today the American Crocodile occurs as isolated individuals or in scattered localized populations along the lower Florida Gulf Coast north of Cape Sable (see map, Fig. 1.) This includes a small consolidated group of adults of unknown origin near Marco

Island, Collier County, that may have been there since the 1960s. (J. Vanas, pers. comm.).

The staff at nearby Rookery Bay National Estuarine Research Reserve has monitored this population since 1997. Nesting has occurred every year since record-keeping began. From 1997 to 2014 a total of 64 American Crocodile nests were recorded, with the greatest number (seven) occurring in 2004. When inspected, well past the normal incubation period, none of these nests contained viable eggs. Apparently a lone 426-cm (est. total length [TL]) male crocodile, thought to be sterile, serves an undetermined number of females in this population. These individuals range between 184 and 365 cm (est. TL). The smallest female is in a size class of her own, the others are nearly twice her size. This individual is thought to be a recent recruit into this population (S. Bertone, pers. comm.).

Carr (1940) lists the crocodile as occurring in Collier County, but Duellman and Schwartz (1958) do not include documentation of *C. acutus* in any of the Southwest Florida counties. Today *C. acutus* is known to regularly occur in all of the Southwest Florida counties and its Gulf Coast range has extended to Lake Tarpon in northern Pinellas County (LeBuff and Lechowicz 2013).

Climate change is considered to be causing the Red Mangrove Tree (*Rhizophora mangle*) to migrate north along both coasts of the Florida peninsula (Proffitt and Travis 2014). *Crocodylus acutus* has a close ecological association with the coastal mangroves in Florida and as this tree slowly progresses northward as the climate warms the American Crocodile will likely continue to extend its range north at an equal pace.

Mazzotti (1989) discusses the nesting success of the American Crocodile in Florida Bay. Although a few of the crocodiles north of the National Park on the Gulf Coast construct nests and deposit eggs, to my knowledge none has been viable. An example of this occurred repeatedly on Sanibel Island, Lee County, in recent years. A *Crocodylus acutus* took up residence on the island's J. N. "Ding" Darling National Wildlife Refuge and was photographically documented by a Refuge visitor in November 1979 (Campbell 1985). This sighting was verified with a second observation, and additional photographs, by George Weymouth and me, respectively, on 6 June 1980.

An adult *Crocodylus acutus* took up residence on nearby Pine Island in a residential neighborhood in late 1985 (Combs 2011). It was never verified but it is suspected that this was the individual first documented on Sanibel. In 1986, Paul Moler of the Florida Game and Freshwater Fish Commission (now Florida Fish and Wildlife Conservation Commission [FWC]) captured, sexed, measured, and marked the Pine Island crocodile. He determined it to be a female measuring 284.48 cm TL. Moler surgically removed the keel of a caudal scute for ease of later identification. After capture the crocodile was relocated to Collier-Seminole State Park, Collier County, about 80 km S of Sanibel. Within six months, now recognizable because of the tail disfigurement, the individual returned to Pine Island but soon moved across Pine Island Sound to Sanibel Island where it is assumed it spent the rest of its life. During those 24 years there were some years without documentation of the animal's presence on the island because there were no sightings reported to wildlife officials. The crocodile had started to move about the island's mangrove system on the Refuge and spent more and more time in the interior freshwater wetlands system known as the Sanibel Slough. This inter-habitat movement was verified by confirmed sightings.

In May 1995 this individual constructed a nest mound with landscape mulch as a substrate at a private residence adjacent to the Refuge (about 370 m from where the crocodile was first photographed in 1979) and deposited eggs. Frank Mazzotti of the University of Florida was consulted by the Refuge and in September he visited the site and removed 47 infertile eggs from the nest. Without a conspecific mate this crocodile continued her fruitless nesting efforts several years through 2009 (J. Combs, pers. comm.). One would expect successful nesting by *C. acutus* to occur in Southwest Florida in the future, commensurate with climate change and, over time, a more balanced sex ratio.

The Piper Brothers and American Crocodiles

Soon after opening their wildlife attraction, the Pipers began to enlarge their American Crocodile collection by responding to an occasional public complaint from persons in the region who felt threatened by the mere sight of a rare wild crocodile. They would travel to capture "nuisance" American Crocodiles as far north as Sarasota County. The last documented one was a 243.8 cm leucistic female *Crocodylus acutus* that Lester and his adult son, David, captured near Osprey, Sarasota County, in 1953 (LeBuff 1957).

There is some anecdotal evidence that a large American Crocodile netted by commercial mullet fishermen in 1936 in McIntyre Creek, a red mangrove tidal creek on Sanibel Island, Lee County, ended up in the Bonita Springs collection. It was this individual that initially motivated the Pipers' interest in crocodiles. However, the majority of their *C. acutus* originated from the stocks in southern Dade and northern Monroe counties. The collection grew quickly after the Pipers (Fig. 2.) made it known they would buy any crocodile caught in Florida.

In 1936 *Crocodylus acutus* was not well protected in Florida and was not protected at all in Monroe County until 1947, commensurate with the establishment of Everglades National Park that year. After 1947, with the American Crocodile protected, the primary source for live *C. acutus* in Florida was eliminated. Thereafter few were collected in Florida unless by institutional applicants which the State of Florida granted collection permits; however, Jamaican *C. acutus* were regularly imported for the live animal trade until the species was protected under provisions of the US Endangered Species Act in 1975. In Florida, *C. acutus* was reclassified and its status was changed from Endangered to Threatened in 2007.

The King Maker

The Piper brothers' chief crocodile supplier was a legendary "Gladesman," one William Argyle Hendry (Fig. 4.). Hendry was born in 1869 in Polk County and moved to Monroe County in the early 20th century. In the later part of his life he went to live on Key Largo (Rock Harbor), Monroe County, where he lived until his death in 1954. He regularly robbed American Crocodile nests of their eggs and caught entire groups of neonates. He sold hatchlings to motoring tourists in-season from a roadside stand on US Highway 1 (The Overseas Highway) and advertised them on signage as "baby alligators." At his home, Hendry built a small pole-lined corral in the water in which he placed the large crocodiles he managed to catch alive in the southern Everglades. The adult animals brought him the best prices; in 1939 he sold a 220-cm *C. acutus* for US $35.00, equivalent to US $582.00 in 2014.

The market he reached consisted of zoological parks, museums, and private collectors.

Argyle (his preference) Hendry had an unusual method for landing adult crocodiles. He used a hooking technique that is much the same as modern Licensed Alligator Trappers use in Florida (Faherty 1949). But in the event crocodiles were not adequately impaled by the sharp treble snatch hooks he threw in their direction, and they managed to escape and retreat into their dens, Hendry applied a unique methodology he had in his basket of tricks. He was widely known among his fellow Gladesmen for his quirky labor-intensive approach (Figs. 5 and 6). Few targeted crocodiles evaded Argyle Hendry's clutches. The following description is condensed from *Florida Wildlife* magazine (LeBuff 2008):

"After locating the entrance of a crocodile's underwater burrow, Hendry swung into action. He removed the floorboards from his skiff and used them to blockade the cave's entrance. The boat was pushed against this makeshift fence to reinforce the floorboard plug should a crocodile try to rush the entrance in an escape attempt.

"Several long steel rods were unloaded from his skiff. Hendry stuck one rod into the ground and forced it down until it broke through into the cave. Next, he pressed the steel rod against his throat and grunted with his mouth closed. He was skilled at creating the exact sounds made by crocodiles. This sound traveled down the metal shaft, and was amplified inside the chamber. If a crocodile was in the den, it would grunt in response. This sound would be transmitted up to Hendry's ear and the response vocalization let him know that a crocodile was at home.

"If he heard a grunt, Hendry withdrew the probe and moved further in from the burrow's entrance and again forced the rod into the soil. He methodically surveyed the width and course of the cave and followed the direction of the tunnel. When he felt firm crocodile hide at the end of his probe, he knew he had successfully herded the reptile to the inner end of its den. Hendry worked additional rods down on either side of his probe, until the full width of the tunnel was barred.

"Hendry used an axe and cleared away vegetation then took a shovel and dug until he broke through the den's ceiling. Once the hole was large enough, Hendry dropped a noose on the crocodile's snout. Using a pole, he worked the loop completely around the animal's jaws and pulled it taut. Next, he'd create a series of half-hitches to lock the toothy jaws together." (Fig. 6)

After an individual crocodile was untethered and secure inside his home corral, Hendry would send a letter to whoever had ordered a specimen and was next in line to buy a crocodile. He not only supplied *Crocodylus acutus* to the Pipers but also to major North American zoos and museums. One of his crocodiles was taken to the Milwaukee Public Museum in 1942 (Dickinson 1953). A fabricated replica of this animal remained on display in a habitat exhibit there in 2014 (C. Jacobson, pers. comm.).

The totality of Argyle Hendry's take of live *Crocodylus acutus* over his five-decade hunting career certainly was a serious impact and directly contributed to the decline in the total population and the number of nesting females remaining in the wild after 1947. Hendry's total take of individual crocodiles is unknown. He randomly removed all sexes and size classes of *C. acutus* from the core of its North American population's stronghold in the mangroves of the upper Florida Bay region for a half-century. Although purchasing American Crocodiles was completely legal, Bill and Lester Piper may be considered today to be complicit in the species' decline. They eagerly bought every crocodile Hendry ever offered them for over a decade. The number of nesting female American Crocodiles estimated to exist in the wild in Florida was 20 in the mid-1970s (Ogden 1978). By the late 1950s the Piper collection held twice that number of sexually mature female *C. acutus*.

Crocodile Caretaking

By early 1953 when I became an employee of EWG, the Pipers' American Crocodile collection contained about 50 adults, 80 juveniles, and a dozen or so captive-reared young of the year (LeBuff 1957). The water used in the various enclosures originated from deep artesian wells and the pressure from any one of the five wells on the property was regulated by a series of valves and auxiliary pumps when needed. The temperature of this water as it discharged from the wells was a constant 22.2°C year-round. Logs on their depth and water quality (chloride concentrations) are unavailable, but the well water likely originated in the lower Tamiami aquifer. The water was well-infused with sulfur dioxide gas and patrons often complained about the strong odor. Recent well-monitoring records suggest saltwater intrusion may not have impacted the water's quality 50 years ago, but it has since (Schmerge 2001). Fifty years ago the water flowing into the crocodile enclosure was potable and similar artesian wells were used for households throughout the Bonita Springs community, including the three dwelling units at EWG.

Water temperatures were never recorded in the crocodile enclosures at EWG any distance from their artesian inlets. Once water dispersed from the inlet it eventually drained via a fixed overflow and discharged into a drainage ditch that led to the Imperial River. The enclosure's water would equalize with the ambient air temperature. The water temperature basically fluctuated commensurate with the daily changes in temperature of the sun-heated water.

Lester Piper (Fig. 8.), who managed the day-to-day business operation of EWG, faithfully monitored weather forecasts. This was essential because winter temperatures could suddenly plummet as the result of a cold front and seriously impact many of his cold-sensitive wards. He knew that sufficiently lowered temperatures could cause mortality among his crocodiles unless he took preventive measures.

Each spring there would be a great deal of sexual activity among the captive crocodiles during which major battles raged between rival males. Two >430-cm (TL) males were permanently exiled to smaller enclosures; the first circa 1948, the second in 1956. The second was removed after it grabbed, vigorously shook, and disemboweled the leucistic female noted earlier.

I recall after this happened I asked Bill Piper (Fig. 7.), "In your opinion which would win in a fight between an alligator and a crocodile?" He thought for a moment and responded, "If they were both adult males and of equal length, the crocodile would win. American Crocodiles like to grab hold and shake their adversary to pieces quickly. The alligator gets a tight grip on the tail or a limb and spins on its body's axis. Alligators kill piecemeal. A crocodile usually goes for its prey or opponent's midsection and gets the job done quicker."

There were no dry areas available in the crocodile's enclosure for egg-laying until the mid-1980s when a sand-filled annex with an opening in a common wall was connected and gave gravid females an opportunity to move into the new compartment to nest. Prior to the addition of the nesting area females deposited

their eggs directly into the water. Staff routinely made a serious effort to retrieve eggs before they were broken and even eaten by the crocodiles. In the 1950s a large tin can with drain holes punched in its bottom was attached to a long pole. At dawn, should crocodiles be observed retrieving and eating eggs, I, or another Gardens employee, would spend up to an hour trying to blindly scoop eggs from the concrete bottom of the deepest section of the

FIG. 7. Bill Piper and his Florida Black Bear (*Ursus americanus floridanus*), "Tom." This photo was taken in Ocala National Forest (Florida) on the movie set during filming of *The Yearling* in 1946. Tom was one of the bears to play the part of "Ol' Slewfoot" in the movie. Visit the EWG link at www.sanybel.com to see a video of Tom in action.

enclosure. It was this section where eggs were usually deposited. Those that were dipped out and were found not to be cracked were buried in an open-air artificial nest mound composed of a sand/sphagnum mixed substrate in hopes of successful hatching. To my knowledge the last clutch of *Crocodylus acutus* eggs produced at EWG that were collected after being submerged yet proved to be viable, were collected in April 1954 and hatched in July. After 1954 there was not a serious continuity in egg retrieval or incubation. Following construction of the nesting annex, crocodiles nested therein at least twice, but the eggs did not hatch (K. Morrison, pers. comm.).

Why captive crocodiles in Bonita Springs produced viable eggs at one time and none are known to do so in the wild today in Southwest Florida warrants investigation. From my experience of over 60 years with Southwest Florida crocodilians most of the *C. acutus* that have moved up the Gulf Coast north of Marco Island, Collier County, during the last half-century are females. More recently, there is evidence that there is a growing number of male *C. acutus* recruits entering the habitat as the species continues to extend its range further north in Southwest Florida (M. Parry, pers. comm.).

In the mid-1990s, Lou Hinds, then manager of J. N. "Ding" Darling National Wildlife Refuge, suggested that a sex-specific translocation effort be made to introduce a male crocodile from South Florida to the Refuge. This proposal never came to fruition because the Florida Fish and Wildlife Conservation Commission (FWC) and the US Fish and Wildlife Service (FWS) had policies in place that prohibited such relocation. It is the opinion of some biologists that FWC considered only that the introduction of a male to Sanibel Island would result in a potential increase in the number of "nuisance" crocodiles that they would have to deal with in the region (M. Westall, pers. comm.). There were several other considerations: 1) During this time there was a known male *C. acutus* nearby in the Caloosahatchee estuary and officials were hopeful that the male and the Sanibel female would find each other without human intervention; 2) State officials were of the opinion an introduced male would immediately move and try to find its way back to its home territory; 3) It was the policy of FWC and FWS not to move any American Crocodile unless that animal exhibited aggressive behavior. Moving an aggressive animal into an area with many people (Sanibel Island) was considered unwise; 4) There was concern by FWC and FWS that relocating a crocodile to a populated area would meet with public concern. This could backlash against endangered species programs, and the latitude to move crocodiles would be lost through politics (L. Hinds, pers. comm.).

The second consideration may not have been valid. An adult female (250.19 cm) nuisance crocodile, considered to be nonaggressive, was captured near Englewood, Charlotte County in May 2010. After magnets were applied to its head, in an experimental attempt to confuse its direction-finding ability, FWC released it on J. N. "Ding" Darling National Wildlife Refuge after approval by FWS. In 2014, this animal remains on Sanibel Island about 8.5 km from its release point (P. Tritaik, pers. comm.).

Introduction of a male crocodile to Sanibel Island, one never exposed to people and therefore an animal which could not be considered a nuisance, would have been an awesome experiment in wildlife management. It is worthy of consideration when such circumstances occur in the future.

FIG. 8. Lester Piper in the late 1940s with one of his tame captive-bred Florida Panthers (*Puma concolor coryi*).

American Crocodiles and Winter Cold

In the event of a winter weather forecast that suggested the imminent incursion of cold temperatures, Lester Piper connected a 5.8-cm flexible pipe to the artesian well serving the crocodile enclosure and increased the flow to distribute more of the "warmer" well water into the enclosure as air temperatures fell. Even in December 1962 when air temperatures officially recorded by the National Weather Service at Page Field, near Fort Myers (25.1 km N of Bonita Springs, and the closest temperature-monitoring facility) were -3.33°C and 1.1°C, respectively, for 13 and 14 December 1962. The captive crocodiles at EWG survived without mishap. Mazzotti et al. (2007) mention a small number of crocodile mortalities in extreme southern Florida during hard freezes. In particular they cite such a weather event in late 1989. At Page Field, Fort Myers, on 24 December 1989, the recorded low was -2.22°C with no known crocodile deaths in the region.

In 2010, American Crocodiles in South Florida were again severely impacted by cold weather and according to the media an estimated 200 wild crocodiles in waters south of Homestead, Florida, succumbed to the extremely low temperatures. On 11 January 2010, the low at Homestead (180 km S of Fort Myers) was recorded at -0.61°C. The minimum temperature near Lake Tarpon (Tarpon Springs), Pinellas County, on 11 January 2010 was recorded at -1.66°C. State wildlife officials knew that a crocodile had been there for "about a year" when it was captured for relocation in 2013, but it is unknown if it was present in the lake and managed to survive the 2010 cold.

According to T. Crutchfield (pers. comm.), when *Crocodylus acutus* is cold-stunned while remaining in the water the affected individual loses control of its nasal valves. These relax to an open

position which allows water to enter the crocodile's respiratory system and drown it. A literature search failed to provide any corroborative source (F. Mazzotti, pers. comm.).

The official minimum temperature recorded at Page Field, Fort Myers, by the US Weather Bureau during the 2010 cold spell was -0.55°C on 11 January. A centrally-located weather station on Sanibel Island at J. N. "Ding" Darling National Wildlife Refuge (not present in 1962) registered a low of 0.55°C on the same date (P. Ryan, pers. comm.). This is higher than the mainland temperature, which is normal and expected because of the influence of slightly warmer tidal waters surrounding Sanibel Island. The resident female *Crocodylus acutus* is thought to be a victim of this low temperature event. This individual's bloated remains were discovered in the interior freshwater wetlands of Sanibel on land owned by the Sanibel-Captiva Conservation Foundation (SCCF) on 26 January 2010 by a member of the SCCF staff. This was 15 days after the blast of cold air reached South Florida. When the crocodile died, its body was almost completely out of the water. About 30.5 cm of the tail remained in the water (C. Lechowicz, pers. comm.). To me this is unusual because at EWG the captive group retreated into the water during cold snaps. This was apparently because the amount of well water entering at such critical times was sufficient to maintain the water at a higher temperature than the air. The reverse apparently occurred on Sanibel when the animal retreated from the water and was exposed to the falling air temperature, became immobilized, and possibly died because of hypothermia; however, age may have played a role in this crocodile's demise, which might have been coincidental to the low temperature. It is noteworthy that as far as I have been able to determine this individual was the largest female *C. acutus* ever recorded in Florida—360 cm TL (LeBuff and Lechowicz 2013). The crocodile had grown 85.52 cm since Moler measured and recorded its length 24 years earlier.

This individual's skeletal remains were skillfully rearticulated and are now part of a permanent exhibit in the Education Center at J. N. "Ding" Darling National Wildlife Refuge.

Bill and Lester Piper dissolved their partnership in 1981 and as part of the settlement Lester obtained title to the Gardens property and animals. After Lester Piper's death in 1992, extended Piper family members assumed management of EWG. By this time the original *Crocodylus acutus* caught by Argyle Hendry and most of their captive-bred offspring had died-off and the younger Piper's acquired a few Jamaican *C. acutus* for the Gardens from the Arthur Jones crocodilian collection near Ocala, Florida.

The EWG that the American public knew and enjoyed for 77 years closed in 2013. Most of the animals were sold to other wildlife exhibits in Florida (including any remaining crocodiles) and the property listed for sale by a realtor. Today, a landscape photographer leases the property and exhibits a few birds, turtles, and small alligators. It is primarily a botanical garden and continues to use the name EWG.

Acknowledgments.—I regularly share my crocodile memories with a cadre of fellow former EWG employees. Like me they had the awesome experience of knowing, working alongside with, and being mentored by Bill and Lester Piper, and helping them keep their American Crocodiles. Only one of us (Trew) ever met Argyle Hendry. I had those opportunities as a young man in the 1950s. The following individuals are also surviving Piper employees from that era, and some have been my friends for over 65 years. We still share conversations about our personal interactions with the remarkable group of American Crocodiles and "America's Crocodile Kings." I appreciate knowing Richard Beatty, Warren Boutchia, and Ralph Curtis, my brother Laban LeBuff, Dennis Morgan, Ken Morrison, Don Trew, Jim Vanas, and George Weymouth. We were all American Crocodile wranglers in our youth and share those memories each December when we gather at Lester Piper's graveside on his birthday. We cannot honor Bill Piper in a similar way for he was cremated and his remains were spread over local waters, but he is often thought of fondly by each of us.

Betty Anholt of Sanibel kindly proofread my draft and asked questions that enhanced the final outcome. James Murphy of the Smithsonian National Zoological Park provided valuable commentary as my manuscript developed. Crocodilian specialist Frank Mazzotti of the University of Florida reviewed the final draft and offered some constructive suggestions.

***DESMOGNATHUS AENEUS* (Seepage Salamander)**. USA: GEORGIA: Crawford Co.: 90–150 m E of Rowland Rd. at its crossing of Hartley Branch (32.68513°N, 83.88709°W; WGS84). 08 July 2014. B. Battistella, S. Graham, and S. Riddle. Verified by Carlos Camp, John Jensen, and David Laurencio. Auburn University Natural History Museum (AUM 40692–40694). New county record (Jensen et al. 2008. The Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.).

Locality is ca. 5–6 km SE of the Fall Line (the boundary between the Piedmont and Coastal Plain physiographic provinces), and extends the range ~60 km SE of the nearest known population in Talbot Co., Georgia (Graham 2009. Herpetol. Rev. 40:232–233). Although a few populations of *D. aeneus* are known from the Coastal Plain in Alabama (Mount 1975. The Reptiles and Amphibians of Alabama. Auburn Printing Co., Auburn. 368 pp.), this is the first population known from this physiographic province in Georgia (Jensen et al. 2008, *op. cit.*). There is notable herpetofaunal species richness in the vicinity of this locality, with certain northern/montane-associated species and Coastal Plain-associated species reaching their southernmost and inland-most parts of their ranges, respectively (Graham et al. 2010. Southeast. Nat. 9:19–34). This new record is no exception; it is ca. 12 km further S than the previous southernmost known population in Chilton Co., Alabama (AUM records).

BETSY BATISTELLA (e-mail: edb0003@auburn.edu) and **SIDNEY RIDDLE**, Department of Biological Sciences, Auburn University, 101 Rouse Life Science, Auburn, Alabama 36849, USA (e-mail: sbr0005@auburn.edu); **SEAN P. GRAHAM**, Department of Biology, Geology, and Physical Sciences, Sul Ross State University, Alpine, Texas 79832, USA (e-mail: sean.graham@sulross.edu).

***NOTOPHTHALMUS MERIDIONALIS* (Black-spotted Newt)**. MÉXICO: SAN LUÍS POTOSÍ: Municipality of Tamasopo: Agua Buena (21.95905°N, 99.392142°W; WGS84), 360 m elev. 10 November 1973. UASLP Agronomy students. Verified by Joel Vázquez Díaz. Zoological Collection, Instituto de Investigación de Zonas Desérticas, Universidad Autónoma de San Luis Potosí (CZIIZD-UASLP 1095 [lot of four samples]). First municipality record, extending the known range ca. 47 airline km W of the closest known locality at 1.6 km E Los Sabinos, Ciudad Valles, San Luis Potosí (Lemos-Espinal and Dixon 2013. Amphibians and Reptiles of San Luis Potosí. Eagle Mountain Publ., Eagle Mountain, Utah. 300 pp.). Although Flores-Villela et al. (2008. The IUCN Red List of Threatened Species. Version 2014.1. <www.iucnredlist.org>. Downloaded 22 July 2014) reported that the species has not been found more than 130 km inland, our record extends that to 176 km inland. However, the possibility exists that the Agua Buena population is extirpated, because none have been found since 1973, even though the site has been visited frequently. The newts were collected in an area covered with tropical semi-deciduous moist forest.

***ANAXYRUS AMERICANUS* (American Toad)**. USA: TENNESSEE: Sullivan Co.: Steele Creek Park Wetlands, ~200 m from Rooster Front Parking Area along the lakeside trail (36.5621°N, 82.2243°W; WGS84). 4 March 2004. M. Kevin Hamed. Verified by A. Floyd Scott. David H. Snyder Museum of Zoology, Austin Peay State University (APSU 19509, photo of live individual). New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Internet version [http://www.apsu.edu/amatlas]; accessed 05 August 2014). Adult was observed with ~250 other American Toads of which ~50 pairs were in amplexus and depositing eggs.

M. KEVIN HAMED, Virginia Highlands Community College, P.O. Box 828, Abingdon, Virginia, 24212, USA; e-mail: khamed@vhcc.edu.

***ANAXYRUS WOODHOUSII* (Woodhouse's Toad)**. USA: COLORADO: Teller Co.: DOR near Fourmile Creek 0.3 km N and 0.17 km W the ghost town of Marigold (38.6628124°N, 105.2237474°W; NAD83; elev. 2093 m). 21 August 2014. Lauren J. Livo, Harry Taylor, and Steve Wilcox. Verified by Bradley Lambert. University of Colorado (UCM Ancillary Collection AC-181 1–3, digital vouchers). First county record (Hammerson 1999. Amphibians and Reptiles in Colorado, 2nd ed. University Press of Colorado, Niwot, Colorado. 484 pp.). Extends the range approximately 16–20 km from the nearest records in Fremont Co.

LAUREN J. LIVO, 1835 S. Van Gordon Street, Lakewood, Colorado 80228 USA; e-mail: LJLivo@aol.com.

***DIAGLENA SPATULATA* (Duck-bill Hylid Frog)**. MEXICO: NAYARIT: Municipio Santiago de Compostela: Sierra de Vallejo (21.02793°N, 105.12292°W; WGS84), 270 m elev. 23 June 2013. Guillermo A. Woolrich-Piña. Verified by Julio A. Lemos-Espinal. Museo de Zoología, Unidad Académica de Agricultura, Universidad Autónoma de Nayarit (MZUAN 158,159). First municipality records and a range extension of ca. 31 km NE of the closest known locality, ca. 6 km SE of Sayulita, Municipality of Bahia de Banderas, Nayarit (Webb 1971. J. Herpetol. 5:185–187). The two adult males were found around 1017 h in a temporary pond formed the previous night.

Field work was supported by the PROMEP project "Los vertebrados de la Sierra de Vallejo" (to JPRS) and CONACyT (postdoctoral fellowship to GAWP).

***ELEUTHERODACTYLUS* (=*SYRRHOPHUS*) *MARNOCKII* (Cliff Chirping Frog)**. USA: TEXAS: Presidio Co.: Sierra Vieja Mountains, Camp Holland (30.548798°N, 104.660618°W; WGS84). 15 August 2014. Jacob D. Owen and Thomas L. Marshall. Verified by Thomas J. Devitt. Texas Natural History Collections (TNHC 92330). This specimen represents a northwestward range expansion of the previously recognized westernmost boundary of this species in Texas, and represents the first vouchered specimen from the Sierra Vieja Mountains in northwestern Presidio Co. (Jameson and Flury 1949. Texas J. Sci. 1:54–79; T. J. LaDuc, pers. comm.). Adult male (SVL 32 mm; 2.2 g) found crossing dirt road near Carriage House at Camp Holland at 2321 h.

We recognize this specimen as *E. marnockii* based on phenotypic similarity to individuals from the Edwards Plateau, following Milstead et al. (1950. Texas J. Sci. 2:543–562). This species had previously been heard calling in canyons at this locality; however, collection attempts over the last 60 years have been unsuccessful (Jameson and Flury 1949, *op cit.* and T. J. LaDuc, pers. comm.). To the best of our knowledge, only two other voucher specimens of this species have been collected in Presidio Co., both in 1968 from San Esteban Lake (19.3 km SE of Marfa, Texas; Texas Cooperative Wildlife Collections [TCWC] 26056, 26057), ~74 km SW of Camp Holland. The next nearest locality of this species is from two specimens collected in 1964 from Musquiz Canyon, SE of Fort Davis (likely where it bisects the Arkansas and Puertacitas Mountains; TCWC 81651, 81652) in southeastern Jeff Davis Co., ~88 km E of Camp Holland. These four TCWC specimens are currently catalogued as *E. guttilatus*.

Specimen collected under a Texas Parks and Wildlife Scientific Research Permit (SPR-1097-912) issued to Travis J. LaDuc. We thank the Miller family for their continued support and assistance.

JACOB D. OWEN, Department of Biological Sciences, Tarleton State University, Box T-0100, Stephenville, Texas 76402, USA (e-mail: jacob.owen@go.tarleton.edu); **THOMAS L. MARSHALL**, 8801 La Cresada Drive, Apt. 427, Austin, Texas 78749, USA (e-mail: thomlmarshall@gmail.com); **DREW R. DAVIS**, Department of Biology, University of South Dakota, 414 East Clark Street, Vermillion, South Dakota 57069, USA (e-mail: drew.davis@usd.edu).

***ELEUTHERODACTYLUS PLANIROSTRIS* (Greenhouse Frog)**. USA: MISSISSIPPI: Hinds Co.: Jackson (32.31342°N, 90.16976°W; WGS84). 11 June 2014. Wenhua Lu, Tom Mann, and Debora L. Mann. Mississippi Museum of Natural Science (MMNS 10386). Verified by Robert L. Jones. New county record (Dinsmore 2004. Herpetol. Rev. 35:403). A second specimen (MMNS 10475) was found on 29 August, 3 km distant.

Introduced species previously recorded in Mississippi from a greenhouse in Oktibbeha Co. (Starkville), about 180 km NE, and from Harrison Co. (Gulfport) (Dinsmore 2004, *op. cit.*), about 238 km SE. Recently also collected in Jackson Co. (Ocean Springs, Jennifer Y. Lamb, pers. comm.). The specimen captured 11 June was calling from a mound of vegetative debris in a steep, wooded ravine in the Belhaven residential neighborhood. A toe was clipped for DNA analysis. Approximately 5–6 individuals were calling concurrently nearby. One that subsequently escaped was photographed on the leaf of a shrub at the height of approximately 1 m. A brief survey for calling frogs was undertaken by car and on foot in the same neighborhood on the night of 14 June 2014. The species was heard at the collection site and at seven other sites within 1 km. MMNS 10475 was captured from the Belhaven site in the Fondren residential neighborhood when it escaped from a cat. Others were heard calling nearby; the species had previously been heard several blocks to the southwest. The presence of the frogs in multiple locations over a distance of at least 3 km suggests that the species is locally established in Jackson. To our knowledge this represents the most northerly and inland established population. The population apparently survived a cold Winter; the US National Weather Service recorded 62 days between October 2013 and April 2014 when the temperature reached 0ºC or lower in Jackson (National Weather Service, Jackson, MS Weather Forecast Office. http://www.srh.noaa.gov/jan/?n=climate_zone_jan_90_100_degs, updated 12 September2014, accessed 12 September2014). The means of introduction is not known; the Gulfport population is suspected to have arrived on nursery stock (Dinsmore 2004, *op. cit.)*.

DEBORA L. MANN, Millsaps College, Jackson, Mississippi 39210, USA (e-mail: manndl@millsaps.edu.); **TOM MANN** (e-mail: Tom.Mann@mmns.state.ms.us), and **NICK WINSTEAD**, Mississippi Museum of Natural Science, Jackson, Mississippi 39202, USA (e-mail: Nick.Winstead@mmns.state.ms.us); **WENHUA LU**, 6 Swinburne St., Jamestown, Rhode Island 02835, USA (e-mail: theconservationagency@cox.net).

***ELEUTHERODACTYLUS PLANIROSTRIS* (Greenhouse Frog)**. PHILIPPINES: MINDANAO ISLAND: Davao City, Ladislawa Villages (7.09697°N, 125.60933°E, WGS84; 32 m elev.). 4 May 2014. Christina A. Olson and Arvin C. Diesmos. Verified by Fred Kraus. National Museum of the Philippines (PNM 9088–9097). First detected through its distinct advertisement call, 24 October 2013, several individuals of both male and female frogs found under landscape plants and garden rocks in residential area of large, urban city. A follow-up survey on 4 May 2014 indicated an established population, with frogs observed in area of at least four blocks (~10 ha). Ten individuals collected. A review of Philippine non-native amphibians did not include records of this species (Diesmos et al. 2010. J. Environ. Sci. Manag. 9:411–53). Because

of its cryptic call and appearance, individuals may be introduced to new localities and overlooked until population is established (Olson et al. 2012. Biol. Inv. 14:889–900). Inquiries with local residents indicate that this population may have been in the area for at least two to five years. First record for Philippines and Southeast Asia, extending its non-native range in Pacific Basin. Nearby localities with introduced populations include Guam and Hawaii; it is native to Cuba, Cayman Islands, and Bahama Islands (Olson et al. 2012. Pac. Sci. 66:255–270).

CHRISTINA A. OLSON, #9 Bauhinia Circle, Ladislawa Villages, Buhangin, Davao City 8000, the Philippines (e-mail: caolson78@gmail.com); **ARVIN C. DIESMOS**, Herpetology Section, Zoology Division, National Museum of the Philippines, Padre Burgos Avenue, Ermita 1000, Manila, Philippines; **KAREN H. BEARD**, Utah State University, Wildland Resources Department, 5230 Old Main Hill, Logan, Utah 84322-5230, USA.

***ELEUTHERODACTYLUS* (*EUHYAS*) *PLANIROSTRIS* (Greenhouse Frog)**. HONDURAS: La Paz: Hotel Del Angel, La Paz, (14.321117°N, 87.676800°W; WGS84), 650 m elev. 24 June 2013. Alexander Gutsche and James R. McCranie. Verified by Mark O. Rödel. Museum für Naturkunde (ZMB 79254–79255). First records for La Paz and only the third Honduran record for this introduced frog. The two previously reported populations are from San Pedro Sula, Cortés (McCranie et al. 2007. Herpetol. Rev. 39:362–363), ca. 140 km NNW of La Paz, and on Guanaja Island, Islas de la Bahía (McCranie and Valdés Orellana 2014. Herpetol. Notes 7:41–49). The two juvenile frogs were discovered at night in a well-watered garden on the hotel grounds. Other juveniles and two adults were also observed in a pool at the site, as well as males calling from inside cracks of a concrete-lined basin protecting water pipes; presence of adults and juveniles indicates an established breeding population. The hotel owners told us that the mostly exotic plants in the garden were trucked to the hotel from a nursery in Tegucigalpa, Distrito Central, Honduras.

Mithapukur (25.6501880°N, 89.1760460°E, WGS84; 35 m elev.). 9 June 2014. Hassan Al-Razi. From paddy field. Adult male. Verified by Jayaditya Purkayastha. Museum of Zoology, Jagannath University, Dhaka, Bangladesh (JnU/ZooM/Amp/2014/0011). First record for Rangpur District, Bangladesh; previously recorded from Saidpur, Nilphamari District (Sarker et al. 2012. Herpetol. Rev. 43:298), and Chittagong (Asmat et al. 2003. Univ. Rajshahi J. Zool. 22:141–143). Current record > 13 km NE from Rangpur and > 35 km NW from Nilphamari, the nearest records. Habitat was *Cynodon dactylon* and *Mangifera indica* plantations.

HASSAN AL-RAZI (e-mail: chayan1999@yahoo.com), **MOHAMMAD ABDUL BAKI**, and **SHAYER MAHMOOD IBNEY ALAM**, Department of Zoology, 3rd Floor, Science Building, Jagannath University 9-10 Chittaranjan Avenue, Dhaka 1100, Bangladesh.

***HYALINOBATRACHIUM FLEISCHMANNI* (Fleischmann's Glass Frog)**. MÉXICO: VERACRUZ: Municipality of Las Choapas: Ejido Piedritas (17.55059°N, 94.13993°W; WGS84), 70 m elev. 2 September 2013. Arturo Arellano-Covarrubias, Uri O. García-Vázquez, and Carlos J. Pavón-Vázquez. Verified by Andrés A. Mendoza Hernández. Museo de Zoología, Facultad de Ciencias (MZFC 28393). First record for the municipality (Aguilar-López and Canseco-Márquez 2006. Bol. Soc. Herpetol. Mex. 14:20–37). The closest reported record is from 108 airline km E at 23.1 mi. S of Pichucalco, Chiapas (Muñoz-Alonso and March Mifsut 2003. Bases de Datos SNIB 2010-CONABIO proyectos No. UO14 y P132). The male was captured at night vocalizing on a palm leaf ca. 2 m above the ground, in tropical evergreen forest directly above a riverbank.

The specimen was taken under a scientific collecting permit issued to Uri O. García-Vázquez by the Secretaría de Medio Ambiente y Recursos Naturales.

CARLOS J. PAVÓN-VÁZQUEZ (e-mail: cjpvunam@gmail.com), **ARTURO ARELLANO COVARRUBIAS,** and **URI O. GARCÍA-VÁZQUEZ**, Museo de Zoología and Departamento de Biología Evolutiva, Facultad de Ciencias, Universidad Nacional Autónoma de México, Ciudad Universitaria, México 04510, DF, México.

***KALOULA TAPROBANICA* (Sri Lankan Bull Frog)**. BANGLADESH: DHAKA DIVISON: Mymensingh District: Bangladesh Agricultural University Campus (24.719625°N, 90.426658°E, WGS84; 147 m elev.). 21 June 2014. Md. Monjurul Islam Talukdar and Md Nurul Islam. Adult at 1930 h from a human-dominated grassland near Fazlul Haque Hall of Bangladesh Agricultural University. Verified by I. Das. Photographic voucher deposited at Lee Kong Chian Natural History Museum (previously Raffles Museum of Biodiversity Research), National University of Singapore (ZRC[IMG] 1.68a–c). Only prior country record is from deciduous forests of Madhupur National Park, Gazipur District, central Bangladesh (Reza and Mahony 2007. Herpetol. Rev. 38:348). This is the first report for Mymensingh District, ca. 160 km E of previous location.

MD. MONJURUL ISLAM TALUKDAR, Department of Food Hygiene and Veterinary Public Health, Bangladesh Agricultural University, Bangladesh Agricultural University, Mymensingh, Bangladesh (e-mail: mithun182003@gmail.com); **MD NURUL ISLAM**, Department of Epidemiology, Chittagong Veterinary and Animal Sciences University. Zakir Hossain Road, Chittagong, Bangladesh (e-mail: nurul@savethefrogs.com); **A.H.M. ALI REZA**, Department of Biological Sciences, Delta State University, Cleveland, Mississippi 38733, USA (e-mail: areza@deltastate.edu).

***LEPTODACTYLUS CHAQUENSIS* (White-lipped Frog)**. BRAZIL: PIAUÍ: Municipality of Floriano: 6.787778°S, 43.041667°W (SAD 69). 6 February 2013, M.S.C.S. Lima. Verified by U. Caramaschi. Museu Nacional, Rio de Janeiro (MNRJ 87532–87534). The species has a wide distribution in South America. Although there are gaps in the known distribution, it has been recorded from Brazil, Paraguay, eastern Bolivia, northern Argentina, and Uruguay. In Argentina and Paraguay, its occurrence is mainly reported to the Gran Chaco formations and its ecotonal regions. In Brazil, its occurrence is known to the states of Acre, Rondônia, Mato Grosso, Mato Grosso do Sul, Minas Gerais, São Paulo, Rio Grande do Sul, and Paraná. More precisely its occurrence in Brazil is confirmed to the ecoregions of Pantanal biome in the states of Mato Grosso and Mato Grosso do Sul and in the Cerrado biome of the states of Mato Grosso, Mato Grosso do Sul, Minas Gerais, and São Paulo, as well as in the transitional ecoregions of the State of Rio Grande do Sul (Frost 2014. Amphibian Species of the World: an Online Reference. Version 6.0. http://research.amnh.org/vz/herpetology/amphibia/; Heyer and Giaretta 2009. Proc. Biol. Soc. Washington 122:292–305). This first state record for Piauí increases the occurrence at least 800 km NE from the Cerrado biomes of Minas Gerais and represents the first record of the species within the Cerrado biome of northeastern Brazil; this suggests that the species is widespread in this Brazilian biome.

***OSTEOPILUS SEPTENTRIONALIS* (Cuban Tree Frog)**. USA. FLORIDA: Santa Rosa Co.: Eglin Air Force Base, 1.06 km WNW of intersection of SR 87 and Vonnie Tolbert Rd (30.471166°N, 86.921091°W; WGS84). 12 June 2014. B. K. Rincon, K. C. Jones. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 173049 photographic voucher and preserved specimen). New county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final report, Project Agreement 08013, Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.) Extends the range roughly 44.5 km ENE of the nearest record in Escambia Co. (UF 170528), and roughly 128.0 km WNW of the second nearest record in Bay Co. (UF 142698).

While conducting an aural survey on 9 June 2014 at 2000 h we heard a single male *Osteopilus septentrionalis* calling. On 12 June 2014 at 2000 h we returned to the same site and used an audio recording of *O. septentrionalis* to locate and capture one male at 2030 h. The frog was calling from a *Cyrilla racemiflora* (titi) branch over an approximately 10 m-long ephemeral pool with native emergent herbaceous vegetation, surrounded by dense shrub thickets on a power line right-of-way. We detected seven other anuran species calling in the vicinity, including *Acris gryllus* (Southern Cricket Frog), *Gastrophryne carolinensis* (Eastern Narrow-mouthed Toad), *Hyla andersonii* (Pine Barrens Treefrog), *H. cinerea* (Green Treefrog), *H. femoralis* (Pine Woods Treefrog), *L. clamitans* (Bronze Frog), and *L. sphenocephalus* (Southern Leopard Frog). Historically, *L. okaloosae* was found here as well. This appears to be the first documented case of *O. septentrionalis* using *L. okaloosae* and *H. andersonii* habitat.

We conducted 12 focused surveys in the surrounding area, in addition to the >140 locations on Eglin AFB that we survey three times annually. We detected no additional *O. septentrionalis*. While isolated individuals could be missed, we concluded that multiple males (i.e., a breeding population) were less likely to be missed. We believe that this specimen represents a lone individual that was transported unintentionally (e.g., on a vehicle) to Santa Rosa Co. from a more established population in peninsular Florida.

BRANDON K. RINCON (e-mail: brandon6@vt.edu), **KELLY C. JONES**, **THOMAS A. GORMAN**, and **CAROLA A. HAAS**, Department of Fish and Wildlife Conservation, Virginia Tech, Blacksburg, Virginia 24061, USA; **JEREMY PRESTON**, Eglin Air Force Base Natural Resources, Niceville, Florida 32578, USA.

***OSTEOPILUS SEPTENTRIONALIS* (Cuban Treefrog)**. USA: FLORIDA: Walton Co.: ~5 km SW Santa Rosa Beach; 0.5 km S jct CR30A/US98 (30.370484°N, 86.274019°W; WGS84). 3 May 2014. M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 33246, adult male). First record for the county and the northwestern-most record for Florida, with the closest record being Bay County (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final report, Project Agreement 08013, Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.).

MATTHEW B. CONNIOR, Health and Natural Sciences, South Arkansas Community College, El Dorado, Arkansas 71730, USA; e-mail: mconnior@southark.edu.

***PSEUDACRIS CRUCIFER* (Spring Peeper)**. USA: TENNESSEE: Sullivan Co.: South Holston Weir Dam Wetland, across from Osceola Island Parking Area along Holston View Dam Road (36.5237°N, 82.1108°W; WGS84). 27 March 2004. M. Kevin Hamed. Verified by A. Floyd Scott. David H. Snyder Museum of Zoology, Austin Peay State University (APSU 19511, photo voucher). New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No 12. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Internet version [http://www.apsu.edu/amatlas]; accessed 05 August 2014). Adult vocalizing in a vernal pool with 75 other Spring Peepers and observed amplexus. I also noted 10 additional adults crossing Holston View Dam Road migrating toward the vernal pool.

M. KEVIN HAMED, Virginia Highlands Community College, P.O. Box 828, Abingdon, Virginia 24212, USA; e-mail: khamed@vhcc.edu.

***PSEUDACRIS NIGRITA* (Southern Chorus Frog)**. USA: GEORGIA: Miller Co.: Mayhaw WMA, primary WMA dirt road, 0.43–0.48 road km N of Griggs Road intersection (31.20073°N, 84.79092°W; WGS84). William W. Booker and Steve J. Hromada. 21 March 2014. Verified by Nikole Castleberry. Georgia Museum of Natural History (GMNH 50698–50699). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.). Two adults (one female, one male) captured swimming or calling in vernal pools within a larger ephemeral wetland. Whole-body, tissue, and digital photo vouchers collected.

Work approved under authority of Georgia DNR Scientific Collecting Permit #29-WJH-13-191 issued on 20 June 2013, and University of Georgia IACUC AUP #A2012 10-004-Y1-A0 issued on 27 February 2013. We thank the instructors and students of the UGA Herpetology course for their assistance.

TESTUDINES — TURTLES

***APALONE SPINIFERA* (Spiny Softshell)**. USA: GEORGIA: Catoosa Co.: South Chickamauga Creek east of Sandstone Creek Drive North of Ringgold (34.936030°N, 85.119756°W; WGS84) 8 July 2014. Joshua R. Ennen, Bernie R. Kuhajda, and Brett Albanese. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF-Herpetology 173669 digital color photo voucher). New county record (Jensen et al. [eds.] 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). One adult male captured in a seine.

JOSHUA R. ENNEN (e-mail: jre@tnaqua.org), and **BERNIE R. KUHAJDA**, Tennessee Aquarium Conservation Institute, Chattanooga, Tennessee, USA; **BRETT ALBANESE**, Georgia Department of Natural Resources, Social Circle, Georgia, USA (e-mail: Brett.Albanese@dnr.state.ga.us).

***APALONE SPINIFERA* (Spiny Softshell)**. USA: TENNESSEE: Madison Co.: Jackson, Cypress Grove Nature Park, Wood Duck Lake (35.616972°N, 88.866458°W; WGS84). 28 May 2014. Corey L. Albert and Brian P. Butterfield. Verified by A. F. Scott. David H. Snyder Museum of Zoology, Austin Peay State University (APSU 19500 photographic voucher). New county record (Scott and Redmond 2008 [latest update: 19 May 2014]. Atlas of Reptiles in Tennessee. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/, accessed 28 May 2014). One adult male was incidentally caught with fishing tackle.

BRIAN P. BUTTERFIELD (e-mail: bbutterfield@fhu.edu), and **COREY L. ALBERT**, Department of Biological, Physical, and Human Sciences, Freed-Hardeman University, Henderson, Tennessee 38340, USA.

***CHRYSEMYS PICTA* (Painted Turtle)**. USA: IOWA: Plymouth Co.: Deer Creek Wildlife Management Area (42.71898°N, 96.50965°W; WGS84). 12 June 2014. Alice R. Millikin. Verified by Jessa L. Watters. Sam Noble Oklahoma Museum of Natural History (OMNH 44140). New county record (LeClere 2013. A Field Guide to the Amphibians and Reptiles of Iowa. ECO Herpetological Publishing & Distribution, Rodeo, New Mexico. 349 pp.). This specimen fills a gap in the known distribution of this species in Iowa. Previous records exist from surrounding counties in Iowa (Sioux, Cherokee, Woodbury) as well as to the west in Union Co., South Dakota. Juvenile collected from shallow margin of a reservoir. Specimen collected under a Iowa Department of Natural Resources Fishing License.

ALICE R. MILLIKIN (e-mail: alicemillikin@gmail.com), **ANDREW D. KOCH** (e-mail: andrew.koch@usd.edu), and **DREW R. DAVIS,** Department of Biology, University of South Dakota, 414 East Clark Street, Vermillion, South Dakota, 57069, USA (e-mail: drew.davis@usd.edu).

***CHRYSEMYS PICTA* (Painted Turtle)** USA: SOUTH CAROLINA: Marlboro Co.: Haire Town Rd. (34.784695°N, 79.799319°W; WGS1984). 18 June 2014. James W. Dillman. Verified by Scott Pfaff. Campbell Museum of Natural History at Clemson University (CUSC 2911 in accession folder 1177, photo voucher). New county record (Beane et al. 2010. Amphibians and Reptiles of the Carolinas and Virginia, 2nd ed. University of North Carolina Press, Chapel Hill. 274 pp.; Jeff Camper, pers. comm.). Adult male DOR between two wet swampy areas associated with Whites Creek.

JAMES W. DILLMAN, South Carolina Department of Natural Resources, P.O. Box 23205, Columbia, South Carolina 29224, USA; e-mail: dillmanj@dnr.sc.gov.

***DEIROCHELYS RETICULARIA* (Chicken Turtle)**. USA: ALABAMA: Bullock Co.: Midway, 0.8 km W of AL Hwy 51 intersection (32.07863°N, 85.52514°W; WGS84). 8 August 2011. E. Soehren. Verified by David Laurencio. Auburn University Natural History Museum (AUM AHAP-D 816, digital photo voucher). New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University, Alabama. 347 pp.). Found AOR in center of U.S. Hwy 82 within Midway town limits. Turtle was missing left forelimb, but otherwise showed no signs of injury or poor health. Individual captured, photographed, and released at a pond near the collection site. This record was vetted through examination of online museum holdings (VertNet; HerpNET) and thorough literature review (Zoological Record).

A second Bullock Co. specimen was encountered on the Wehle Forever Wild Tract (AUM AHAP-D 817, digital photo voucher).

ERIC C. SOEHREN, Elhew Field Station, Wehle Land Conservation Center, State Lands Division, Alabama Department of Conservation and Natural Resources, 4819 Pleasant Hill Road, Midway, Alabama 36053, USA; e-mail: eric.soehren@dcnr.alabama.gov.

***GRAPTEMYS OUACHITENSIS* (Ouachita Map Turtle)**. USA: LOUISIANA: West Baton Rouge Parish: southeast side of Addis

(30.356655°N, 91.249009°W; WGS84). 22 March 2014. Brennan Landry. Verified by Jeff Boundy. Louisiana Museum of Natural History (LSUMZ 98350). First parish record (Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge, Louisiana. 300 pp.). Specimen collected in borrow pit in Mississippi River batture.

BRENNAN LANDRY, 535 Avenue A, Port Allen, Louisiana 70767, USA; e-mail: landry.brennan@yahoo.com.

***GRAPTEMYS PSEUDOGEOGRAPHICA KOHNII* (Mississippi Map Turtle)**. USA: LOUISIANA: West Baton Rouge Parish: southeast side of Addis (30.356655°N, 91.249009°W; WGS84). 20–22 March 2014. Brennan Landry. Verified by Jeff Boundy. Louisiana Museum of Natural History (LSUMZ 98351–98353). First parish record (Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge, Louisiana. 300 pp.). Specimens collected in borrow pit in Mississippi River batture.

BRENNAN LANDRY, 535 Avenue A, Port Allen, Louisiana 70767, USA; e-mail: landry.brennan@yahoo.com.

***PLATEMYS PLATYCEPHALA PLATYCEPHALA* (Twist-necked Turtle)**. BRAZIL: AMAZONAS: Municipality of Maraã: Coracizinho stream, at the Amanã Sustainable Development Reserve (2.590833°S, 64.886389°W; WGS84). 01 July 2004. J. Valsecchi. Verified by A. L. C. Prudente. Coleção Herpetológica do Museu Paraense Emílio Goeldi, Belem, Pará, Brazil (MPEG 556), collected in tropical upland forest with a pitfall trap located near a shallow forest pool. Ubim stream, at the Amanã Sustainable Development Reserve (2.4675°S, 64.575278°W; WGS84). 12 April 2014. D. G. Rocha and T. Q. Morcatty. Verified by W. Dutra. Coleção Herpetológica do Instituto de Desenvolvimento Sustentável Mamirauá, Tefé, Amazonas, Brazil (HERPETO 0658), found close to the shoreline of a shallow, muddy, and slow-water stream, in tropical upland forest. Municipality of Jutaí: left margin of Jutaí River, at the Jutaí River Extractive Reserve (3.253056°S, 67.326389°W; WGS84). 11 June 2014. T. Q. Morcatty. Verified by W. Dutra. HERPETO 0659. *Platemys p. platycephala* is potentially distributed in the whole Amazon region (Almonacid et al. 2007. Las Tortugas y los Cocodrilianos de los Paises Andinos del Tropico. Conservacion Internacional, Bogotá, Colombia. 467 pp.) and some specimen collections confirmed its occurrence in Ecuador, Venezuela, Guyana, French Guiana, Surinam, Colombia, Peru, Bolivia, and Brazil (Ernst 1983 J. Herpetol. 17:345–355; Pritchard and Trebbau 1984. The Turtles of Venezuela. SSAR Contrib. Herpetol. No. 2, Oxford, Ohio. 403 pp.; Cisneros 2006 Biota Neotrop. 6:3–16). In Brazil, the species has been recorded from the states of Mato Grosso, Acre, Pará, and Amazonas (Ernst 1983, *op. cit.*; Bernarde et al. 2011 Biota Neotrop. 11[3]:117–144; Molina et al. 2009 Check-List 5[3]:714–716; Ferrara et al. 2009 Herpetol. Rev. 40[2]:236;). In Amazonas state, the species was recorded at the east and west ends of the state, leaving a gap of 1120 km between Manaus and Tabatinga (Ernst 1983, *op. cit.*). The nearest known record to the new records in Maraã is 555 km E, in the lower Amazon River, near Manaus, Amazonas, Brazil (Ernst 1983, *op. cit.*). The new record in Jutaí is 317 km SW of nearest record for the Yavarí River, near Tabatinga, Amazonas, Brazil (Ernst 1983, *op. cit.*). Due to the difficulty of detecting individuals, the distribution of this secretive species is poorly documented, and these records extend its confirmed distribution area to include the central part of the Amazon. License number SISBIO 43620-1 by Instituto Chico Mendes de Conservação da Biodiversidade.

THAÍS Q. MORCATTY (e-mail: tatamorcatty@yahoo.com.br), **JOÃO VALSECCHI** (e-mail: joao.valsecchi@mamiraua.org.br), Instituto de Desenvolvimento Sustentável Mamirauá, Caixa Postal 38, CEP 69553-225, Tefé, Amazonas, Brazil; **DANIEL G. ROCHA**, Instituto Nacional de Pesquisas da Amazônia (INPA), Caixa postal 408, CEP 69011-670, Manaus, Amazonas, Brazil (e-mail: rochadg.bio@gmail.com).

***PSEUDEMYS CONCINNA* (River Cooter)**. USA: TEXAS: Comal Co.: New Braunfels, Landa Lake Park, Comal Springs. (29.713446°N, 98.135651°W; WGS84). 7–20 April 2014. Verified by Carl J. Franklin. Amphibian and Reptile Diversity Research Center, University of Texas at Arlington (UTADC 8191–8193, photo voucher). New county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 447 pp.).

An adult male was captured by hand. This specimen represents a range extension of approximately 350 km from the closest known locality in eastern Texas (Dixon 2013, *op. cit.*). This is not a species that would be considered common in the pet trade. It is unclear if this animal represents an individual release or an established population. We hope that sampling conducted over the next several years will allow us resolve this issue.

North American Freshwater Turtle Research Group (NAFTRG) was conducting its summer long-term turtle population study under permit # SPR-0212-019.

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle)**. USA: ALABAMA: Bullock Co.: Wehle Forever Wild Tract, 6.1 km SE of AL Hwy 51 and Bullock CR 47 (Pleasant Hill Road) intersection. (32.03623°N, 85.46856°W; WGS84). 15 June 2010. E. Soehren and J. Trent. Verified by David Laurencio. Auburn University Natural History Museum (AUM AHAP-D 826, digital photo voucher).

New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University, Alabama. 347 pp.). Adult female found partially covered in leaf litter along trail in open, mature floodplain forest. Individual captured, photographed, and released. This record fills in county gap adjacent to Montgomery, Macon, Russell, and Barbour counties within the upper Coastal Plain region (Mount 1975, *op. cit.*) and was vetted through examination of online museum holdings (VertNet; HerpNET) and thorough literature review (Zoological Record).

ERIC C. SOEHREN (e-mail: eric.soehren@dcnr.alabama.gov), and **JOHN A. TRENT**, Elhew Field Station, Wehle Land Conservation Center, State Lands Division, Alabama Department of Conservation and Natural Resources, 4819 Pleasant Hill Road, Midway, Alabama 36053, USA (e-mail: john.trent@dcnr.alabama.gov).

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle)**. USA: ILLINOIS: Carroll Co.: Thomson Causeway Recreation Area (41.950242°N 90.115769°W; WGS84). 27 July 2014. Sarah M. Mitchell, Julie M. Wiemerslage, Hayley K. Madland, and William A. Manriquez. Verified by Fredric J. Janzen. Iowa State University Amphibian and Reptile Research Collection (ISUA 201401, three digital photographic vouchers). New county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Natural History Survey, Urbana, Illinois. 282 pp.). One adult male (12.2 cm straight line carapace length, 0.79 cm straight line carapace width) was caught in an aquatic hoop trap attached to a 2.5 m seine. The species is documented from adjacent Whiteside Co. to the south (Phillips et al. 1999, *op. cit.*).

Aquatic trapping of turtles has been performed at the Thomson Causeway for approximately 20 years with no previous captures of *S. odoratus*; thus, this specimen may indicate a recent expansion of the range. Alternately, the previous lack of detection of this species could be attributed to trapping bias. Beginning in May 2014, 2.5-cm mesh traps were deployed, which may have increased the likelihood of capture over the 5-cm mesh traps that we used exclusively in the past.

Funding for this work was provided by a grant from the National Science Foundation to F. J. Janzen. Permission to conduct the research was granted by the Illinois DNR, U.S. Army Corps of Engineers, and U.S. Fish & Wildlife Service.

SARAH M. MITCHELL (e-mail: sarahmit@iastate.edu), and **JULIE M. WIEMERSLAGE**, Department of Ecology, Evolution, and Organismal Biology, Iowa State University, 251 Bessey Hall, Ames, Iowa 50010, USA.

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle)**. USA: LOUISIANA: Cameron Parish: Lacassine Bayou, 1.36 river km S of Jefferson Davis/Cameron Parish line (30.026396°N, 92.861902°W; WGS84). 27 August 2013. Cybil C. Huntzinger and Will Selman. Verified by P. Lindeman. Florida Museum of Natural History Herpetology Department (UF 173772 photo archive). New parish record (Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge. 300 pp.).

This record extends the previously documented range southwest approximately 32 km from specimens collected (USNM 100091, 100093) near the town of Mermentau (Jefferson Davis Parish; HerpNet database search, http://www.herpnet.org, accessed 29 May 2014). Individual was captured in a baited, modified crab trap.

SQUAMATA — LIZARDS

***ANOLIS CAROLINENSIS* (Green Anole)**. BRAZIL: BAHIA: Municipiality of Salvador: Ondina (13.007524°S, 38.509230°W, WGS84; elev. 33 m). 23 March 2000. M. S. Tinôco. Setor de Herpetologia, Coleção Herpetológica de Referência do Centro de Ecologia e Conservação Animal, Universidade Católica do Salvador, Salvador, Brazil (CHECOA 000040; survey license SISBIO Nº 23355-2; SVL = 55.1 mm, TL = 20.3 mm, HL = 19.6 mm). *Anolis carolinensis* is native to the southeastern United States (Conant and Collins 1998. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, 3rd ed., expanded. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.). It has been introduced and established on numerous islands in the Caribbean Sea, Pacific Ocean, and Spain (Wiles and Guerrero 1996. Pacific Sci. 50[3]:274–284; Pleguezuelos et al. 2002 *In* Pleguezuelos et al. [eds.], Dirección General de Conservación de la Naturaleza-Asociación Herpetológica, pp. 495–526. Madrid, Spain; Okoschi et al. 2006. Bulletin of FFPRI 5[4]:265–269; Nicholson et al. 2010. Zootaxa 3477:1–108; Norval et al. 2012. Herpetol. Notes 5:95–97). The specimen was found at a small Atlantic forest remnant nearby the local Zoo area, and probably it is a pet that escaped from captivity. There is no evidence for the establishment of this species in the wild, and this is the only record of the species in Brazil.

ÉRICA FONSECA, Universidade Estadual de Santa Cruz – UESC, Campus Soane Nazaré de Andrade, km 16 Rodovia Ilhéus-Itabuna, Ilhéus, Bahia, Brazil (e-mail: erica.fonsecae@gmail.com); **RICARDO MARQUES**, Universidade Estadual de Santa Cruz – UESC, Campus Soane Nazaré de Andrade, km 16 Rodovia Ilhéus-Itabuna, Ilhéus, Bahia, Brazil (e-mail: rcdmarquess@gmail.com); **MOACIR SANTOS TINÔCO**, Programa de Pós Graduação - Planejamento Ambiental - ECOA-UCSAL; The University of Kent at Canterbury – DICE, Marlowe Building, Kent, UK CT2 7NZ (e-mail: moacirtinoco@gmail.com).

***ANOLIS SAGREI* (Cuban Brown Anole)**. USA: CALIFORNIA: San Diego Co.: Vista (33.175°N, 117.236°W, WGS84; elev. 158 m) 19 July 2014. C. Mahrdt, E. Ervin, and L. Geiger. Verified by Bradford D. Hollingsworth. San Diego Natural History Museum (SDSNH 76128–76133). New county and state record (Granatosky and Krysko 2013. IRCF Rept. Amphib. 20[4]:190–191).

Four adult males and two hatchling specimens were collected on a one-acre parcel landscaped with palms, cycads, and several species of tropical plants and ground cover. Several boulders scattered throughout the parcel were used as perch sites for male lizards. An additional 16 adults and six hatchlings were observed in the two-hour site visit (1030–1230 h). Adults were also

observed beyond the property indicating that this population is established and likely expanding through the contiguous tropical landscaping of neighboring properties. According to the property owner, he first observed the species in August 2012 shortly after receiving shipments of palm trees in May–August originating from suppliers located in the Hawaiian Islands.

Additional reports from California include Rancho Mirage and Palm Desert, Riverside Co., and Huntington Beach and Santa Ana, Orange Co. (www.californiaherps.com). The status of these populations is undetermined.

***HEMIDACTYLUS MABOUIA* (Wood Slave)**. USA: FLORIDA: Lake Co.: Eustis, 403 Firewood Avenue (28.83761°N, 81.68091°W, WGS84; elev. 35 m). 5 November 2013. Laurence L. Connor. Verified by Kevin M. Enge. Florida Museum of Natural History (photographic voucher UF-Herpetology 171731). New county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final report, Project Agreement 08013, Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.). First county record and extends the range ca. 40 km NW of the closest known verified voucher (UF-Herpetology 137123) in Orange Co., Florida. This gecko was collected on a residential building, photographed, but subsequently escaped. A second gecko distinguished from the first by a full tail versus a partial tail was observed 20 m NW of the first location on 9 November 2013.

KRYSKO**, Division of Herpetology, Florida Museum of Natural History, 1659 Museum Road, University of Florida, Gainesville, Florida 32611, USA (e-mail: kenneyk@ufl.edu).

***HEMIDACTYLUS TURCICUS* (Mediterranean Gecko)**. USA: KANSAS: Lyon Co.: Emporia, exterior wall at 3032 U.S. 50, Days Inn Emporia (38.411667°N 96.222473°W; WGS84). 18 August 2014. Cameron University Museum of Zoology (CUMZ 233). Jared White. Verified by Greg Sievert. New county record (Collins et al. 2011. Amphibians, Reptiles, and Turtles in Kansas. Eagle Mountain Publishing, Eagle Mountain, Utah. 312 pp.). Multiple adults found on walls of the motel. The nearest documented population is 151 km NE in Johnson Co., Kansas (Hare 2006. J. Kansas Herpetol. 19:9).

JARED W. WHITE (e-mail: Jwhite16@emporia.edu), and **MICHAEL S. HUSAK**, Department of Biological Sciences, Cameron University, Lawton, Oklahoma 73505, USA (e-mail: michaelh@cameron.edu).

***HEMIDACTYLUS TURCICUS* (Mediterranean Gecko)**. USA: TEXAS: Erath Co.: Stephenville city limits (32.22067°N, 98.20491°W; WGS84). 22 July 2014. Jacob Devlin Owen. Verified by Travis LaDuc, Texas Natural History Collections (TNHC 92222). New county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 447 pp.). Juvenile measuring 24+[2] mm and weighing 0.2 g. This record adds to the rapidly expanding range of the introduced *H. turcicus*. Additionally, this species is frequently observed on many structures throughout Stephenville city limits and is potential evidence for an established population. This individual was captured at 2245 h along the wall of the First Baptist Church where the gecko was hunting insects clustering around the lights of the church.

JACOB D. OWEN, Department of Biological Sciences, Tarleton State University, Box T-0100, Stephenville, Texas, USA; e-mail: jacob.owen@go.tarleton.edu.

***HEMIDACTYLUS TURCICUS* (Mediterranean Gecko)**. MEXICO: JALISCO: Municipality of Ocotlán: Ocotlán (20.346244°N, 102.774645°W; WGS84), 1530 m elev. 30 December 2013. Daniel Rigoberto Aceves Lara. Verified by Gunther Köhler. CUCBA, Universidad de Guadalajara, (CZUG-R 305). First record for the state, extending the known range ca. 178 airline km SSW of the nearest locality at Aguascalientes, Aguascalientes (Vázquez-Díaz and Quintero-Díaz 2005. Anfibios y Reptiles de Aguascalientes. CONABIO, CIEMA, A.C., México, D.F. 318 pp.). The adult gecko was found after dark on a building in downtown Ocotlán. Three other adults and two juveniles were also observed at the same locality on the evening of 8 January 2014, which indicates a well-established population.

***HOLBROOKIA ELEGANS* (Pacific Earless Lizard)**. MÉXICO: DURANGO: Municipio Tamazula: 1.84 km SE Tamazula (24.96583°N, 106.94944°W, WGS84), 267 m elev. 29 September 2013. Raúl Muñiz-Martínez. Verified by Julio A. Lemos-Espinal. CIIDIR-DGO 1402. First record for Durango and a 78 km NNE range extension from the closest known locality, 2 mi. (3.2 km) S Obispo, Sinaloa (Goldberg 2010. Texas J. Sci. 62:281–286). The lizard was found in tropical deciduous forest.

RAUL MUÑIZ-MARTINEZ, ROSAURA VALDEZ-LARES and **DAVID RAMÍREZ-NOYA** (e-mail: raulmm1@yahoo.com), Laboratorio de Fauna

Silvestre, CIIDIR-IPN-DGO. Sigma 119, Fracc. 20 de Noviembre II, 34220, Cd. Durango, Durango, México.

***MEDIODACTYLUS KOTSCHYI* (Kotschy's Gecko)**. GREECE: South Aegean Pref.: Arki Island, northwest of main port (37.384411°N, 26.732142°E, WGS84; 35 m elev.). 25 September 2013. Stephanos A. Roussos and Ilias Strachinis. Verified by J. Foufopoulos and P. Lymberakis. Natural History Museum of Crete (NHMC 80.3.85.1664) and University of Michigan Museum of Zoology, Division of Reptiles and Amphibians (Digital Image Collection Number 1229, photographic voucher, one individual). New island record that fills a distributional gap of the most northern island in the Kos-Arki Island chain (Chondropoulos 1986. Amphibia-Reptilia 7:217–235; Broggi 2008. Herpetozoa 21:79–84). Seventeen subspecies have been described for the species across the Aegean region and 14 of them are unique to islands (Chondropoulos 1986, *op. cit.*). Based upon the most proximal population that has been given a subspecific identification the new record could tentatively be considered *Mediodactylus kotschyi beutleri*, which is also present on Kalymnos (Schneider 1983. Salamandra 19:61–70). The closest island to Arki where *M. kotschyi* has previously been found is Lipsi Island, about 7 km S of Arki (Broggi 2008, *op. cit.*). *Mediodactylus kotschyi* is widespread and common across the Cycladic archipelago but on mainland Greece it is only common at specific localities. In the Dodecanese archipelago they are common on small, rocky, and arid satellite islands but rare on the larger islands (Foufopoulos 1997. Herpetozoa 10:3–12). The gecko was found at night, traversing a crevice in bedrock.

STEPHANOS A. ROUSSOS, Department of Biological Sciences, MS 43131, Texas Tech University, Lubbock, Texas 79409-3131, USA (e-mail: sa.roussos@ttu.edu); **ILIAS STRACHINIS**, School of Biology, Aristotle University of Thessaloniki, Thessaloniki, 54124, Greece.

***OPHISAURUS ATTENUATUS* (Slender Glass Lizard)**. USA: ALABAMA: Clay Co.: Talladega National Forest, approximately 4 km N of Campbell Springs at intersection of Adams Gap Road and State Route 281 (Talladega Scenic Highway) (33.40432°N, 85.87459°W; WGS84). 4 June 2014. Brian D. Holt and Kevin Carr. Photographic voucher (AUM AHAP-D 819). Verified by David Laurencio. New county record (Mount 1975. Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University, Alabama. 347 pp.). A single adult, sex unknown, was observed among a small stand of oak-leaf hydrangea at the Adams Gap trailhead. Habitat was dry hardwood forest dominated by oak and hickory with a pine component. This is a species of "moderate conservation concern" for the state (Mirarchi [ed.] 2004. Alabama Wildlife. Volume 1. A Checklist of Vertebrates and Selected Invertebrates: Aquatic Mollusks, Fishes, Amphibians, Reptiles, Birds, and Mammals. University of Alabama Press, Tuscaloosa. 209 pp.). This record fills a gap between Cleburne and Tallapoosa counties within the Piedmont Physiographic Province (Mount 1975, *op. cit.*).

We thank Eric Soehren for reviewing this note and David Laurencio for verifying the identification and confirming the county record.

BRIAN D. HOLT (e-mail: brian.holt@dcnr.alabama.gov), and **KEVIN CARR**, Alabama Department of Conservation and Natural Resources, State Lands Division, Natural Heritage Section, 64 N Union Street, Suite 464, Montgomery, Alabama 36130, USA.

***OPHISAURUS ATTENUATUS LONGICAUDUS* (Eastern Slender Glass Lizard)**. USA: ALABAMA: Coosa Co.: Mitchell Lake, island in Hatchet Creek, Alabama Power Company, 5.7 km NW of AL Hwy 22 and Coosa CR 27 intersection (32.85602°N, 86.41414°W; WGS84). 8 May 2009. E. Spadgenske, E. Soehren, and R. Fitch. Verified by David Laurencio. AUM AHAP-D 806 (digital photo voucher). New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University, Alabama. 347 pp.). Individual captured on island in Hatchet Creek backwater of Mitchell Lake impoundment. Island dominated by mature, montane *Pinus palustris* (Longleaf Pine) under a frequent burn regime. This record was vetted through examination of online museum holdings (VertNet; HerpNET) and thorough literature review (Zoological Record).

A second Coosa Co. specimen (AUM AHAP-D 807),was found on the Coosa Wildlife Management Area.

ERIC W. SPADGENSKE, Partners for Fish and Wildlife Program, U.S. Fish and Wildlife Service, 1208-B Main Street, Daphne, Alabama 36526, USA (e-mail: eric_spadgenske@fws.gov); **JOHN A. TRENT** (e-mail: john.trent@dcnr.alabama.gov) and **ERIC C. SOEHREN**, Elhew Field Station, Wehle Land Conservation Center, State Lands Division, Alabama Department of Conservation and Natural Resources, 4819 Pleasant Hill Road, Midway, Alabama 36053, USA (e-mail: eric.soehren@dcnr.alabama.gov); **ROBERT C. FITCH**, Environmental Affairs Department, Alabama Power Company, 600 North 18th Street, Birmingham, Alabama 35291, USA (e-mail: rcfitch@southernco.com).

***PHRYNOSOMA MODESTUM* (Round-tailed Horned Lizard)**. USA: TEXAS: Kent Co.: Lake Alan Henry Wildlife Mitigation Area (LAHWMA); 13 km S, 25 km W Clairemont (33.059834°N, 101.019776°W; WGS84). 24 June 2013. Stephen Kasper. Verified by Carl J. Franklin. Amphibian and Reptile Diversity Research Center, University of Texas at Arlington (UTADC 8195–8197; digital vouchers). New county record at the eastern extent of its range (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 447 pp.). The lizard was found in a creek tributary of the South Fork of the Double Mountain Fork of the Brazos River on red Holocene sands that were eroded from the Permian formation canyon slopes. In over 14 years of field observations, this is only the second individual identified by me for LAHWMA and the county.

STEPHEN KASPER, Lake Alan Henry Wildlife Mitigation Area, Parks and Recreation Department, City of Lubbock, Lubbock, Texas 79401, USA; e-mail: skasper@mail.ci.lubbock.tx.us.

***PHRYNOSOMA SOLARE* (Regal Horned Lizard)**. USA: ARIZONA: Gila Co.: State Route (SR) 188, 24.2 km SE of SR 87 (33.850°N, 111.311°W, NAD 1927; elev. 715 m). 30 July 2014. Brian K. and Elizabeth A. Sullivan. Verified by T. R. Jones. Museum of Vertebrate Zoology observation (MVZ obs Herp #17 photo voucher). Extends the range ~25 km (by air) E of the recognized range along the western fringe of the Mazatzal Mountains in eastern Maricopa Co. (Brennan and Holycross 2006. A Field Guide to Amphibians and Reptiles in Arizona. Arizona Game and Fish Department, Phoenix. v + 150 pp.). Adult male DOR on the eastern slopes of the Mazatzal Mountains near Lake Roosevelt.

Additional DOR specimens were observed (by BKS) at this precise locality in 2007, and more or less continuously to the north and northwest along SR 188 and SR 87 at additional localities over a distance of 30 km, including one in the vicinity of Rye, Arizona, in 2005 (34.087°N, 111.358°W, NAD 1927; elev. 960 m). Habitats along SR 188 range from diverse upland Sonoran Desert scrub as evidenced by abundant Saguaro (*Carnegiea*

gigantean) and Palo Verde (*Parkinsonia florida, P. microphylla*) near Lake Roosevelt to heavily grazed, semi-desert grassland dominated by Acacia (*Acacia greggii*) and Mesquite (*Prosopis velutina*) at higher elevations (~ 1000 m) near Rye. Seed harvester ant nests (*Pogonomyrmex* spp.) were present at all sites where horned lizards were observed.

Maricopa Co.: Hummingbird Spring Wilderness (33.643°N, 113.139°W; NAD 83; ele. 603 m). 26 August 2013. Keith Sullivan and Hunter McCall. Verified by T. R. Jones. Museum of Vertebrate Zoology observation (MVZ obs Herp #16 photo voucher). The Hummingbird Spring specimen extends the range 32 km SW and 24 km SE of the nearest Arizona localities, the vicinity of Wickenburg and the Harquahala mountains, respectively (Brennan and Holycross 2006, *op. cit.*), and reduces the apparent gap within the distribution of this lizard in western Maricopa Co. and central Arizona. These lizards and others observed over the course of two months of fieldwork were in rocky, upland Sonoran Desert scrub. Specimens from Hummingbird were not collected as they were found in a wilderness area, but both horn number and color pattern clearly distinguishes this taxon from the only other congener in the area, *P. platyrhinos*.

BRIAN K. SULLIVAN (e-mail: bsullivan@asu.edu), and **ELIZABETH A. SULLIVAN**, Arizona State University, Phoenix, Arizona 85069,USA; **KEITH O. SULLIVAN** and **HUNTER McCALL**, Contracts Branch, Arizona Game and Fish Department, Phoenix, Arizona 85086, USA.

PHYLLOPEZUS PERIOSUS. BRAZIL: CEARÁ: Municipality of Brejo Santo: 7.55593°S, 38.84170°W (WGS84). 3 May 2014. Municipality of Mauriti: 7.37946°S, 38.64663°W. 12 November 2013. Municipality of Missão Velha: 7.22268°S, 39.14426°W. 20 March 2014. Municipality of Icó: 6.24613°S, 38.66390°W. 21 December 2013. A. F. S. Neta, A. J. M. G. Ferreira, and H. F. Oliveira. Verified by I. J. Roberto. Coleção Herpetológica da Universidade Regional do Cariri, Crato, Ceará, Brazil (URCA-H 8925, 6844, 8204, 9003, respectively; collecting permits ICMBio 29613-1). This gecko is an endemic species of northeastern Brazil, being reported from the states of Alagoas (Piranhas Municipality), Bahia (São João Municipality), Paraíba (Cabaceiras and Congo municipalities), Pernambuco (Sítio dos Nunes, Flores and Ibimirim municipalities), Ceará (Nova Jaguaribara and São João do Jaguaribe municipalities), and Rio Grande do Norte (Serra Negra do Norte Municipality) (Rodrigues 1986. Pap. Avul. Zool. 36:237–250; Freire et al. 2000. Herpetol. Rev. 31:54; Roberto and Brito 2004. Herpetol. Rev. 35:409; Ferreira et al. 2011. J. Threat. Taxa Comm. 3:1990–2000; Lima et al. 2011 Salamandra 47:227–228). These records extend the distribution, taking as reference the municipality of Icó, Ceará, ca. 195 km S airline from the municipality of Nova Jaguaribara, Ceará, ca. 215 km N from Sitio dos Nunes, municipality of Flores, Pernambuco, and ca. 306 km W from Cabaceiras, Paraíba.

THAWLEY, Department of Biology, Pennsylvania State University, 208 Mueller Laboratory, University Park, Pennsylvania 16802, USA (e-mail: cthawley@gmail.com); **FERN GRAVES,** School of Forestry and Wildlife Sciences, Auburn University, Auburn, Alabama 36849, USA (e-mail: fbg0002@auburn.edu).

SQUAMATA — SNAKES

***AGKISTRODON CONTORTRIX LATICINCTUS* (Broad-banded Copperhead)**. USA: TEXAS: Erath Co.: County Road 296 just west of Farm to Market Road 914 (32.037°N, 98.242°W; WGS84), approximately 25.1 km S of Stephenville, Texas. 21 July 2014. Jacob D. Owen, Jesse M. Meik, Maranda McGonigle, and Colt Hamilton. Verified by Travis LaDuc. Texas Natural History Collections (TNHC 92221). New county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps, 3rd ed. Texas A&M University Press, College Station, Texas. 447 pp.). Female measuring 513+[86] mm SVL (with incomplete tail) and weighing 124.9 g, found crossing a gravel road (north to south) at 2222 h in habitat dominated by yucca and honey mesquite vegetation surrounded by cattle ranches. This new record fills in a distributional gap between adjacent counties.

JACOB D. OWEN (e-mail: jacob.owen@go.tarleton.edu), **MARANDA McGONIGLE** (e-mail: maranda_m@msn.com), **COLT HAMILTON** (e-mail: gamingninja@ymail.com), and **JESSE M. MEIK**, Department of Biological Sciences, Tarleton State University, Box T-0100, Stephenville, Texas 76402, USA (e-mail: meik@tarleton.edu).

***AGKISTRODON PISCIVORUS LEUCOSTOMA* (Western Cottonmouth)**. USA: ARKANSAS: Marion Co.: ~6 km SE Rush (36.092481°N; 92.503929°W; WGS84). 1 August 2014. M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (photo voucher ASUMZ 33254, adult). First county record, filling a distributional hiatus between adjacent Baxter and Searcy counties (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.).

MATTHEW B. CONNIOR, Health and Natural Sciences, South Arkansas Community College, El Dorado, Arkansas 71730, USA; e-mail: mconnior@southark.edu.

***AGKISTRODON RUSSEOLUS* (Yucatecan Cantil)**. MÉXICO: TABASCO: Municipio Emiliano Zapata: Nuevo Pochote (17.838383°N, 91.693036°W; WGS84), 18 m elev. 19 February 2014. P. Charruau, A. H. Escobedo Galván, and M. A. Morales Garduza. Verified by M. A. López Luna. Colección de Anfibios y Reptiles de Tabasco, División Académica de Ciencias Biológicas, Universidad Juárez Autónoma de Tabasco (CART 00702). First record for Tabasco, extending range in Mexico ca. 190 km SSW from 5 km S Champotón, Campeche (Gloyd 1972. Proc. Biol. Soc. Washington 84:327–334); it is also known from near La Libertad, Petén, Guatemala (Campbell 1998. The Amphibians and Reptiles of Northern Guatemala, the Yucatán, and Belize. Univ. Oklahoma Press, Norman. xix + 380 pp.). The species was recently elevated from a subspecies of *A. bilineatus* to a full species by Porras et al. (2013. Amphib. Rept. Conserv. 7:48–73). The snake was found in an area containing pastures and secondary vegetation. Four other individuals were observed near this locality in rice fields and low semi-evergreen forest of *Haematoxylon campechianum* (Logwood). The species is locally called Nauyaca Guatemalteca, Vibora Cabeza de Jicotea, or Wolpoch.

Field work was funded by the Secretaría de Energía, Recursos Naturales y Protección Ambiental (SERNAPAM), Consejo Nacional de Ciencia y Tecnología (CONACYT) and Gobierno del Estado de Tabasco through project Fondo Mixto TAB-2012-C28-194316.

***ARIZONA ELEGANS* (Glossy Snake)**. USA: TEXAS: Williamson Co.: TX FM 619, ~0.16 km N jct with CR 490 (30.437259°N, 97.259584°W; WGS84). 19 May 2014. Thomas L. Marshall. Verified by Travis J. LaDuc. Texas Natural History Collections (TNHC 92392 [TJL 2648]). New county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps, 3rd ed. Texas A&M University Press, College Station, Texas. 447 pp.). This specimen fills a gap in the known distribution of this species in Texas. Previous records exist from adjacent Travis, Bastrop, Lee, and Milam counties. The closest known locality to this recently collected individual is ~15 km S in Bastrop Co. (14.5 km E Elgin; Natural History Museum of Los Angeles County [LACM] 106986). Adult male (SVL: 990 mm, tail length: 174 mm, 361.1 g) found dead on road at 2110 h.

Specimen collected under a Texas Parks and Wildlife Scientific Research Permit (SPR-1097-912) issued to Travis J. LaDuc.

THOMAS L. MARSHALL, 8801 La Cresada Drive, Apt. 427, Austin, Texas 78749, USA; e-mail thomlmarshall@gmail.com.

ARRHYTON TAENIATUM. CUBA: CAMAGÜEY: Municipality of Nuevitas: Sabana-Camagüey Archipelago, Sabinal Key (21.6736°N, 77.2767°W; WGS84). 1999 (complete date not listed). W. Vilató Viamontes. Verified by Luis V. Moreno. Herpetological Collection of the Instituto de Ecología y Sistemática, Habana, Cuba (CZACC 4.5910). First record for Sabinal Key and first from a non-mainland site. The nearest locality on mainland Cuba is 118.3 km SE at Holguín city (Schwartz and Garrido 1981. Ann. Carnegie Mus. Nat. Hist. 50:207–230). The snake was found in a grassland habitat.

ADONIS GONZÁLEZ and **MANUEL ITURRIAGA**, División de Colecciones Zoológicas, Instituto de Ecología y Sistemática, Carretera de Varona km 3 ½, Capdevila, Boyeros, AP 8029, CP 10800, La Habana, Cuba (e-mail: manueliturriaga@ecologia.cu).

***CEMOPHORA COCCINEA COPEI* (Northern Scarletsnake)**. USA: OKLAHOMA: Pushmataha Co.: Clayton off St. Hwy. 2 (34.597217°N, 95.344141°W; WGS84). 15 October 1988. M. Roberts. Verified by S. E. Trauth. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 33274). New county record (Oklahoma Biological Survey, Distribution of Oklahoma Amphibians and Reptiles by Recorded Sightings [DOKARRS Search], http://www/snomnh.ou.edu; Sam Noble Oklahoma Museum of Natural History Reptile Database [SNOMNH Search], http://www.snomnh.ou.edu). Other *Cemophora c. copei* from the state are housed in the SNOMNH from adjacent Atoka, Le Flore, McCurtain, and Pittsburg counties.

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, Idabel, Oklahoma 74745, USA; e-mail: cmcallister@se.edu.

***COLUBER* (= *MASTICOPHIS*) *FLAGELLUM* (Coachwhip)**. USA: ALABAMA: Bullock Co.: Wehle Forever Wild Tract, 5.4 km SE of AL Hwy 51 and Bullock CR 47 (Pleasant Hill Road) intersection (32.03834°N, 85.47552°W; WGS84). 15 May 2007. E. Soehren and J. Trent. Verified by David Laurencio. Auburn University Museum of Natural History (AUM AHAP-D 818, digital photo voucher). New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University, Alabama. 347 pp.). Individual encountered crossing sandy road within fire-maintained open pine community. Specimen captured, photographed, and released; fills in county gap adjacent to Macon, Russell, Barbour, and Pike counties within the upper Coastal Plain region (Mount 1975, *op. cit.*). This record was vetted through examination of online museum holdings (VertNet; HerpNET) and thorough literature review (Zoological Record).

ERIC C. SOEHREN (e-mail: eric.soehren@dcnr.alabama.gov), and **JOHN A. TRENT**, Elhew Field Station, Wehle Land Conservation Center, State Lands Division, Alabama Department of Conservation and Natural Resources, 4819 Pleasant Hill Road, Midway, Alabama 36053, USA (e-mail: john.trent@dcnr.alabama.gov).

***COLUBER* (= *MASTICOPHIS*) *FLAGELLUM FLAGELLUM* (Eastern Coachwhip)**. USA: FLORIDA: Hamilton Co.: Suwannee Ridge Mitigation Park Wildlife and Environmental Area (30.44366°N, 83.04613°W; WGS84). 4 April 2014. Jonathan D. Mays. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 173272, digital photographic voucher). First record for the county (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final report, Florida Fish and Wildlife Conservation Commission, Tallahassee. 524 pp.). Adult male trapped by a drift fence installed in sandhill habitat.

JONATHAN D. MAYS (e-mail: jonathan.mays@myfwc.com), **CODY D. GODWIN,** and **KEVIN M. ENGE**, Florida Fish and Wildlife Conservation Commission, 1105 S.W. Williston Road, Gainesville, Florida 32601, USA.

***CONOPHIS VITTATUS* (Striped Road Guarder)**. MÉXICO: MÉXICO: Municipio de Tonatico: El Zapote (18.7568889°N, 99.61172222°W; WGS84), 1522 m elev. 16 March 2012. Oswaldo Hernández-Gallegos and Juan Manuel Carmen-Cristóbal. Verified by Uri Omar García Vázquez. Museo de Zoología, Facultad de Ciencias (MZFC 26547). First confirmed record for the State of Mexico (Wellman 1963. Univ. Kansas Publ. Mus. Nat. Hist. 15:251–295; Aguilar-Miguel et al. 2009. Ciencia ergo sum 16:171–180), with the nearest reported locality to El Zapote positioned 22.4 km S Ixtapan de la Sal, Guerrero (Wellman 1963, *op. cit.*). Vegetation at the locality is tropical deciduous forest interspersed with agricultural crops.

OSWALDO HERNÁNDEZ-GALLEGOS, Centro de Investigación en Recursos Bióticos, Facultad de Ciencias, Universidad Autónoma del Estado de México, Instituto Literario 100, Toluca Centro, Estado de México, México, C.P. 50000 (e-mail: ohg@uaemex.mx); **JUAN MANUEL CARMEN-CRISTÓBAL**, **JAIR RICARDO MALVAEZ-ESTRADA**, **CARLOS ALEJANDRO RANGEL-PATIÑO**, **GISELA GRANADOS-GONZÁLEZ**, and **MARÍA DE LOURDES RUIZ-GÓMEZ**, Facultad de Ciencias, Universidad Autónoma del Estado de México, Instituto Literario 100, Toluca Centro, Estado de México, México, C.P. 50000.

***CROTALUS HORRIDUS* (Timber Rattlesnake)**. USA: ARKANSAS: Searcy Co.: vic. Mull, ~3 km S of Jct AR 14/ Ramblewood Trail (36.052048°N, 92.594601°W; WGS84). 31 August 2014. M. B. Connior. Verified by S. E. Trauth. Arkansas State University Museum of Zoology Herpetology Collection (ASUMZ 33270, photo voucher). New county record partially filling a distributional hiatus among previous records in Marion, Baxter, and Stone counties in northern Arkansas (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville. 421 pp.).

MATTHEW B. CONNIOR, Health and Natural Sciences, South Arkansas Community College, 300 S. West Ave., El Dorado, Arkansas 71730, USA; e-mail: mconnior@southark.edu.

***CROTALUS MOLOSSUS MOLOSSUS* (Northern Black-tailed Rattlesnake)**. USA: ARIZONA: Yuma Co.: Tinajas Altas Mountains, unnamed canyon on public land (32.270475°N, 114.051541667°W; WGS84), elev. 483 m. 2 May 2009. Chip Cochran, Austin I. Steagall, and Myke Clarkson. Verified by George L. Bradley. UAZ Sonoran Herpetological Photographic Voucher Initiative (UAZ 57585-PSV). First record for the Tinajas Altas Mountains and southwesternmost record for this species in USA, extends the known range ca. 37 km SE of the Gila Mountains (UAZ 45465-PSV) and ca. 30 km W of the Cabeza Prieta Mountains (UAZ 55306-PSV, 55308-PSV). The adult male was found with a coil exposed from underneath a rock in a side canyon surrounded by Lower Colorado River Desertscrub, Sonoran Desert Scrub (Brown 1994. Biotic Communities of the Southwestern United States and Northwestern Mexico. University of Utah Press, Salt Lake City. 342 pp.), at 1200 h. Ambient 1.5 m temperature was 25.0°C, humidity at 1.5 m was 34.5%, substrate temperature was 26.6°C, cloud cover was thin and covered 75% of the sky.

***NERODIA CYCLOPION* (Mississippi Green Watersnake)**. USA: ARKANSAS: Lincoln Co.: Cane Creek State Park, Boat Ramp at Cane Creek Lake (33.916525°N, 91.76517°W; WGS84). 27, 29 June 2014. T. J. Fayton. Verified by V. V. Tkach. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 33420) and Henderson State University Collection (HSU 1743). New county record filling a gap in the Delta among previous records for adjacent Arkansas, Desha, Drew, and Jefferson counties (Trauth et al. 2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.). This snake has now been reported from 19 counties of the state.

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); **HENRY W. ROBISON**, 9717 Wild Mountain Drive, Sherwood, Arkansas 72120, USA (e-mail: hwrobison@yahoo.com); **STANLEY E. TRAUTH**, Department of Biological Sciences, Arkansas State University, State University, Arkansas 72467, USA (e-mail: strauth@astate.edu); **RENN TUMLISON**, Department of Biology, Henderson State University, Arkadelphia, Arkansas 71999, USA (e-mail: tumlison@hsu.edu).

***PANTHEROPHIS EMORYI* (Great Plains Ratsnake)**. USA: TEXAS: Kimble Co.: 3.6 km W on CR 120 from Highway 377 (30.315922°N, 99.952986°W, WGS84; elev. 633 m). 26 May 2012. Stephanos A. Roussos, Michael Sager, and Brandon Gross. Verified by Llewellyn D. Densmore III and Carl Franklin. Amphibian and Reptile Diversity Research Center, University of Texas at Arlington (UTA DC 8133, 8134, photographic vouchers). New county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps, 3rd ed. Texas A&M University Press, College Station, Texas. 447 pp.). Fills a distributional gap among Menard, Mason, Gillespie, Kerr, Edwards, Sutton, and Schleicher counties. The species is widespread throughout central Texas and Kimble Co. is in the middle of the known distribution (Dixon 2013, *op. cit.*). The individual was caught, measured and blood sampled (Llewellyn D. Densmore III laboratory collection, Department of Biological Sciences, Texas Tech University; catalog ID LD1281) before being released at the exact location of capture.

STEPHANOS A. ROUSSOS, Department of Biological Sciences, MS 43131, Texas Tech University, Lubbock, Texas 79409–3131, USA; e-mail sa.roussos@ttu.edu.

***PANTHEROPHIS GUTTATUS* (Red Cornsnake)**. USA: ALABAMA: Coosa Co.: Coosa Wildlife Management Area: Cahaba & Columbiana Forever Wild Tracts, 4.7 km NNW of AL Hwy 22 and Coosa CR 29 intersection at Kellys Crossroads (32.87600°N, 86.35409°W; WGS84). 21 May 2014. E. Soehren. Verified by David Laurencio. Auburn University Museum of Natural History (AUM AHAP-D 808, digital photo voucher). New county record (Mount 1975. The Reptiles and Amphibians of Alabama. Agricultural Experiment Station, Auburn University, Alabama. 347 pp.). Individual observed in a non-viable *Picoides borealis* (Red-cockaded Woodpecker) artificial cavity insert about 3.7 m up bole of mature *Pinus palustris* (Longleaf Pine). Snake viewed and videoed using a peeper scope while performing cavity checks. The cavity is regularly occupied by *Glaucomys volans* (Southern Flying Squirrel) and likely the reason it was found in the insert. This record fills a gap between eastern Chilton and Clay counties in the Piedmont physiographic province (Mount 1975, *op. cit.*) and was vetted through examination of online museum holdings (VertNet; HerpNET) and thorough literature review (Zoological Record).

JESÚS SIGALA-RODRÍGUEZ,** Universidad Autónoma de Aguascalientes, Centro de Ciencias Básicas, Departamento de Biología, Avenida Universidad No. 940, Aguascalientes, Aguascalientes 20131, México; **RUBÉN A. CARBAJAL-MÁRQUEZ**, Centro de Investigaciones Biológicas del Noroeste, C.P. 23090, La Paz, Baja California Sur, México.

***THAMNOPHIS MARCIANUS* (Checkered Gartersnake)**. USA: ARIZONA: Santa Cruz Co.: San Rafael Valley, ca.18.5 km SW Patagonia (31.45156° N, 110.58923°W, NAD83; elev. 1480 m). Thomas R. Jones and Amy Bailey. 2 August 2007. Verified by G. Bradley. University of Arizona Herpetological Collection (UAZ 57379). First from the San Rafael Valley headwaters of the mainstem Santa Cruz River. MVZ 76663–76664; HerpNet, http://www.herpnet.org/ [accessed 21 May 2014]; A. T. Holycross, pers. comm.)

Two additional individuals have been observed within the Valley: one unvouchered animal DOR ca. 1.3 km W of this site, 24 July 2007 by R. J. Timmons, and one captured, marked, and released 27 August 2012 on the Santa Cruz River ca. 11 km S, by M. Braun and T. R. Jones. In adjacent Sonora, Municipio de Cananea, *T. marcianus* was observed but not vouchered 18 August 2008 on a dirt road crossing of the Río San Rafael, a tributary to the Río San Pedro, 24.8 km NNE Cananea (31.171870°N, 110.266030°W) by J. C. Rorabaugh, A. D. King, and S. MacVean, and on 21 August 2008 on a dirt road ca. 12 km NNE of Cananea (31.07395°N, 110.24474°W) by J. C. Rorabaugh.

The nearest known records elsewhere in the upper Santa Cruz River drainage are on Sonoita Creek about 18 km NW on the north side of the Patagonia Mountains (MVZ 76663–76664, *op. cit.*), and in the upper San Pedro River drainage near Elgin, beyond the Canelo Hills, about 18 km NNE (numerous recent records; TRJ, pers. obs.). However, *T. marcianus* has not been documented from Sonoita Creek since 1967, (Turner 2007. Son. Herpetol. 20:38–42). The Sonora observations are 37 km and 45 km SE of the southernmost San Rafael Valley site, within a southeastern extension of the grasslands that comprise the San Rafael Valley in Arizona and form a drainage divide between the headwaters of the Santa Cruz and San Pedro rivers. The nearest previously documented *T. marcianus* in Sonora are from "Cananea" (1946, AMNH 67257, 67259) and "Cananea and vicinity" (2005, UAZ 26877–78, 2005) in the Río San Pedro or Río Sonora drainages, ca. 60 km SE of the 2007 record and ca. 20 km S of the 2008 Sonora observation.

All individuals were found in a plains grassland community (Brown 1982. Desert Plants 4:115–121), in an area where aquatic habitats have received considerable scrutiny in the past three decades (e.g., Collins et al. 1988. *In* Szaro et al. [eds.] Management of Amphibians, Reptiles and Small Mammals in North America, pp. s45–53. Rocky Mountain Forest and Range Experiment Station, Fort Collins, Colorado; Jones et al. 1988. Copeia 1988:621–635; Storfer et al. 2004. Copeia 2004:783–796; Rorabaugh et al. 2013. *In* Gottfried et al. [compilers], Merging Science and Management in a Rapidly Changing World: Biodiversity and Management of the Madrean Archipelago III and 7th Conference on Research and Resource Management in the Southwestern Deserts, pp. 103–109, Rocky Mountain Research Station, Fort Collins, Colorado), thus it is highly unlikely *T. marcianus* has been overlooked until recently. The distribution of *T. marcianus* been expanding the last few decades (A. T. Holycross, pers. comm.); in several areas they appear to have occupied habitats that previously supported the now rare *T. eques*. These records provide further evidence that *T. marcianus* is extending its distribution within Arizona and possibly adjacent areas of Sonora.

Knowledge of Angolan biodiversity, and especially amphibian and reptile diversity, remains highly incomplete. The first comprehensive works on the Angolan herpetofauna were made during the 19th century by J. V. Barbosa du Bocage, who published a series of short papers on the country's amphibians and reptiles, culminating in his magnum opus "*Herpétologie d'Angola et du Congo*" (Bocage 1895). Following Bocage, Ferreira conducted a number of studies of the Angolan herpetofauna (Ferreira 1897a, 1897b, 1900, 1901, 1903, 1904, 1905, 1906) as did Boulenger (1905, 1907, 1915), Angel (1921), Parker (1936), and Mertens (1938). While the majority of these publications were short and descriptive, Albert Monard contributed more methodical and detailed studies of both Angolan amphibians (Monard 1938) and reptiles (Monard 1937). Subsequent contributions include those of the Pulitzer Expedition to Angola (Boulton 1931; Schmidt 1933, 1936), Bogert (1940) and Loveridge (1944) on the herpetological material of the Vernay Expedition, as well as Hellmich (1957a, b) and Fitzsimons (1959). The most extensive recent data are presented in a series of publications by Raymond Laurent (1950, 1954, 1964) based on the rich collections of the Museu do Dundo in northern Angola. Contributions during the late Portuguese colonial period and post-independence have been limited. These include papers by Horton (1972) and Gans (1976) and recent post-civil war contributions from several South African and European herpetologists (Haacke 2008; Conradie et al. 2012, 2013; Ernst et al. 2013). Frétey et al. (2011) recently published a list of Angolan amphibians, but based largely on previously published data. The general lack of recent work is due in part to the violent civil war that devastated the country for decades. New studies on the diversity, distribution, and ecology of Angolan amphibians and reptiles are urgently needed especially for conservation assessments.

As part of a broader program to review existing knowledge of the herpetofauna of Angola, we visited the Museu Nacional de História Natural in Luanda (MNHN), Angola, in December 2012 and December 2013 to study its herpetological collections. The museum's scientific (i.e., non-exhibit) collections are dominated by a single large collection of fishes, amphibians, reptiles, and some mammals made by one of us (A. Lavres), a biologist from the Museum, from January to April 2003 during the construction of a dam in the Capanda region, Malanje Province, as already noted by Kuedikuenda and Xavier (2009). The amphibians and reptiles of this area have not been explored previously and, due to the flooding of the area, the collection constitutes an interesting source of information about this area's herpetofauna prior to this major disturbance. Further, due to the extended period during which the collection was assembled and to the large numbers of specimens collected, the data from this collection may provide important baseline data to understand the impacts of the dam on the fauna in this northern region of the country.

Brief History of the Museu Nacional de História Natural and its Collections

The MNHN is a museological descendant of the Angolan Museum, founded in Luanda in 1938 and established in São Miguel Fort in the Luanda Bay area. The first plan for the creation of the Angolan Museum was published by Fernando Mouta (1936). Mouta, a Portuguese engineer based in Luanda at that time, had been contacted by Swiss zoologist Albert Monard (1886–1952) who had explored Angola on two different occasions: first between July 1928 and February 1929, and second between April 1932 and October 1933. Based largely on the latter expedition, Monard published extensively about Angolan amphibians and reptiles (Monard 1937, 1938), birds (Monard 1934), and mammals (Monard 1935). Inspired by the rich and unexplored biodiversity of the country, Monard devised and presented a plan to erect a Natural History Museum in the region, and offered to direct and manage the museum himself. Mouta (1936) promoted the idea of Monard becoming the director of such an institution, but for unknown reasons this did not happen. In 1938 the Angolan Museum opened to the public in São Miguel Fort. The institution was not exclusively dedicated to natural history; it contained archeological collections, weaponry, religious art, a small ethnographic collection, and a large library with rare books and historical documentation, as well as the nucleus of a natural history collection (Anonymous 1950). These last collections were transferred during the mid-1940s to the *Liceu* (public high school) of Luanda due to a lack of space and appropriate facilities to maintain it, and also to meet the educational need for a collection for use in classes (Anonymous 1950). Only in 1956 did the colonial government decide to build a new museum in Luanda dedicated exclusively to Natural History. There is relatively little published or archival information available about this new building and museum, and its history is yet to be written. What is known from the personal communication of people who knew the museum in that time is that its collections were prepared mostly by a taxidermist from the Museu de História Natural Álvaro de Castro Museum in Lourenço Marques (now Maputo), Mozambique. The museum was designed as a typical twentieth century museum, with the majority of the specimens presented in large, colorful, and well prepared dioramas. Since its inception, the MNHN has

FIG. 1. The diorama halls of the Museu Nacional de História Natural in Luanda, Angola.

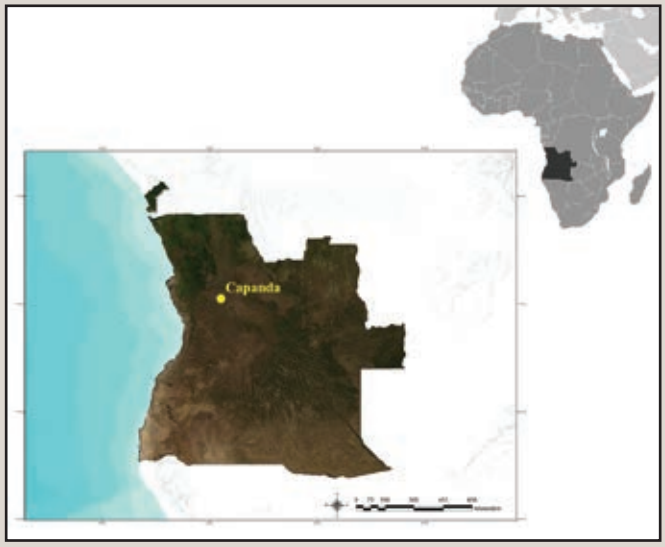

FIG. 2. Map of Angola, with Capanda indicated by a yellow circle.

been mostly devoted to public exposition and education. This stands in contrast to its Mozambican counterpart, as well as to the Museu do Dundo, at which the biological laboratory was directed by the Portuguese entomologist António Barros de Machado (1912–2002) and where the herpetological collections were used for scholarly investigation by several well known scientists, including Raymond Laurent. Pinto (1983) referred to zoological expeditions carried out by the Museu de Angola in 1941, 1944, 1946, 1950, 1956, and 1959, when at least birds were collected. Although some of those birds may have gone to the museum dioramas as exhibition specimens, the vast majority were deposited in the former Instituto de Investigação Cientifico de Angola (IICA), as were specimens collected by subsequent expeditions like those from the Hamburg Museum in 1954 and the British Museum in 1957. All of these scientific collections are now housed in the Lubango Museum in southern Angola (Mills et al. 2010). From the mid-1950s to the independence of the country in 1975, the Museum remained as a public exhibition museum, and after independence it became the MNHN. Since then, it has been maintained primarily as a public exhibition place (Fig. 1). However, in 2003, while conducting environmental impact studies in the Capanda region, Malanje Province, where a dam was to be built, investigators from MNHN collected several hundred specimens of fishes, amphibians, reptiles, and mammals. This collection, besides a small fish collection, constitutes the only scientific collection present at the museum, and was originally discussed in an unpublished report and has not been critically reviewed by herpetologists (Kuedikuenda and Xavier 2009). Additional field trips in other provinces of Angola have also produced small collections, especially of reptiles, in the MNHN that have likewise not been studied. The Museum building is currently facing several structural problems, and urgent repair works are planned.

MATERIALS AND METHODS

Study site.—Capanda Dam is part of the hydroelectrical dam established in the Kwanza River basin in the province of Malanje, Angola (Fig. 2). The entire area is situated between 870 and 1000 m elevation, and the dam is situated in the municipality of Cacuso (the dam wall is located at 9°47.48'S, 15°27.58'E).

With a length of 960 km, the Kwanza River is the longest river with both its source and mouth in Angola. Its source is in the north of Mumbué (Bié Province), at an elevation of approximately 1500 m. The Kwanza has 15 major tributaries: Lucala, Mucoso, Lombe, Cuije, Cuque, Luando, Cuíva, Cuíme, and Chimbamdiango entering the right bank and Gango, Cutato, Cinhinga, Lúbia, Cunje, and Cuquema entering the left bank. The Duque de Bragança Falls in Malanje Province are located on one of these tributaries, the Lucala (Pinto 1983). The complete extent of this hydrographic basin extends to 152,570 km^2. The average annual rainfall of this region varies between 1300–1400 mm, and average annual temperatures range from 18–20ºC (Pinto 1983). The surrounding vegetation in the area of the dam is typical for Malanje. Pinto (1983) refers to this habitat as "open forests, *Brachystegia* woodlands." The vegetation is dominated by approximately 50 large tree species, chiefly *Julbernardia paniculata* (Fabaceae) and five species of the genus *Brachystegia* (Fabaceae). These trees, whose crowns are usually large and sometimes contiguous, can reach heights of 6–18 m, depending on the nature of the soil and amount of rainfall. In addition, there are about 100 small tree and bush species and 300–400 species of grasses, sedges, and non-woody plants (Pinto 1983).

Data collection.—This collection was made by one of us (A. Lavres) and three technicians from the MNHN from January to April 2003 while conducting other field work related to the Capanda Dam project. Searches were made on both banks of the Kwanza River, in the flood zone, during the day, generally from 0800 to 1600 h. Most specimens were collected opportunistically by hand and every specimen was fixed in 20% formalin in the field and later transferred to 70% ethanol. An unpublished list (available in the museum), apparently made immediately after the fieldwork, lists a total of 136 specimens of amphibians, 154 snakes, 8 chelonians (all with the note "released"), and 463 lizards. The majority of the specimens in the collection today (a total of 254 amphibians and 310 reptiles) are associated with reference numbers, either on their bottles or on specimen tags, but these numbers are not linked to any existing catalog in the Museum nor clearly referable to those in the above-cited list. Therefore, for all the specimens present we developed new reference numbers, identified all the bottles with labels bearing the reference number of each specimen, and developed an internal catalogue for the museum. They are cited here by these

new reference numbers. Some specimens stored in jerry cans in the museum are still awaiting catalog numbers due to the lack of material (bottles, tags, etc.) for re-bottling and are here noted as "uncat. JC." The situation is far from ideal but reflects one facet of the reality of biodiversity research in this region of Africa.

Results

Species Accounts

AMPHIBIA
ANURA
BUFONIDAE

Amietophrynus* cf. *regularis (Reuss, 1833)

Material. 182 specimens: MNHNL/ANF/A/Amy 1–182

Comments. These specimens likely represent *Amietophrynus regularis,* which remains a taxonomically challenging species. Multiple species may be present among these specimens but the level of preservation of some specimens precludes more precise identification. The species is widespread within Angola (Monard 1938; Laurent 1964; Ruas 1996), across much of sub-Saharan Africa, and extending north along the Nile Valley (Rödel 2000; Frétey et al. 2011). It has been previously recorded from a diversity of sites across Angola by Bocage (1895), Mertens (1938), Laurent (1950, 1954, 1964), and Hellmich (1957a). Bocage (1895) cited *Bufo regularis* from Pungo Andongo, 20 km NE of Capanda.

HYPEROLIIDAE

Hyperolius parallelus (Günther, 1859 "1858")

Material. 44 specimens: MNHNL/ANF/A/Hyp 1–45

Comments. This species is widespread across Angola and occurs in central Africa from the southern Republic of Congo and Democratic Republic of Congo south to western Zambia, northern Namibia and Botswana, and in the Victoria Falls region of Zimbabwe (du Preez and Carruthers 2009; Frétey et al. 2011). It has been reported from Angola by many previous authors though under a variety of names now recognized as synonyms; (e.g., Bocage 1873; Ferreira 1904, 1906; Mertens 1938), and is recorded for several provinces in the country, namely Lunda Norte (Laurent 1952, 1954), Moxico (Laurent 1954), Zaire (Bocage 1977), Bengo (Boulenger 1882), and Huila (Monard 1938).

Specimens 1–26 present a typical *parallelus* dorsal pattern, consisting of a dark dorsum with narrow white dorsal and lateral lines. Specimens 27–45 present a vermiculated dorsal pattern more similar to that of the holotype of *Hyperolius angolensis* Steindachner, 1867. This latter, initially described from a single specimen from Duque de Bragança, approximately 100 km NE of Capanda, is currently considered a synonym of *H. parallelus* by some authors (Frétey et al. 2011; Frost 2014), part of the *Hyperolius parallelus-marginatus* subgroup (Schiotz 1999), as a subspecies of *Hyperolius marmoratus* (Rapp, 1842) (Poynton and Broadley 1987) and as a full species by Channing (2001). Both *H. parallelus* and *H. marmoratus* are taxonomically difficult species. *H. marmoratus,* which is widespread across southern and eastern Africa, appears to be absent from Angola (Channing 2001), even if it has been previously reported from the country under various names (Ferreira 1906; Mertens 1938; Laurent 1943, 1950, 1964), which can be partly explained by the considerable intraspecific and interspecific variation and consequent confusion among these groups. There are several studies in progress on the genus *Hyperolius* and in these taxonomically difficult groups, and we hope these will contribute some clarifications on their identities. Given the current knowledge, we opt to consider these specimens also as part of *H. parallelus.*

Kassina* cf. *maculosa

Material. 1 specimen: MNHNL/ANF/A/K 1

Comments. This juvenile specimen probably represents *Kassina maculosa* (Sternfeld, 1917) because of characteristic pigmentation around the eye and tympanum and the lack of dorsal markings running continuously from the head to vent (du Preez and Carruthers, 2009; Amiet 2012). If correct, then this is first record of the species in Angola. The species is known from Cameroon, the Democratic Republic of Congo, and Central African Republic (Frétey et al. 2011). This would be the southernmost record of the species. Such southern extensions of the Central African amphibian fauna may be more common than previously believed as indicated by the recent records of the "Hairy Frog" *Trichobatrachus* in Angola (Ernst et al. 2014). Laurent (1964) previously commented on the difficulty of identifying those species of *Kassina* in Angola and Central Africa. Two other species have been previously recorded for Angola, *Kassina senegalensis* (Duméril & Bibron, 1841) by Schmidt (1936), Monard (1938), and Laurent (1964), and *Kassina kuvanguensis* (Monard, 1937) by Monard (1938).

PIPIDAE

Xenopus* cf. *petersii (Bocage, 1895)

Material. 25 specimens: MNHNL/ANF/A/Xe 1–25

Comments. These specimens probably represent *Xenopus petersii,* a widespread species distributed across Angola, Zambia, and northern Namibia and Botswana (Laurent 1964; Channing 2001). There are several localities from the Kwanza River below the Capanda Dam (Ruas 1996). The specimens show the characteristic dark blotches across the ventral surface yet these are not as prominent in other specimens of *X. petersii* (see Appendix). The species has been recorded for the region by several authors (Bocage 1895; Ferreira 1906; Ruas 2002), and Ruas (2002) listed it as occurring at Duque de Bragança, currently Kalandula, approximately 100 km NE of Capanda.

PHRYNOBATRACHIDAE

Phrynobatrachus* cf. *natalensis (Smith,1849)

Material. 1 specimen: MNHNL/ANF/A/Pr 1

Comments. This poorly preserved specimen of *Phrynobatrachus* seems to represent *P. natalensis,* a widespread complex of species extending across much of southern Africa including Angola (Channing 2001; Zimkus et al. 2010). There are many previous records across Angola (Bocage 1895, 1897; Ferreira 1904; Boulenger 1905; Parker 1936; Schmidt 1936; Monard 1938; Laurent 1950, 1954, 1964; Hellmich 1957a; Ruas, 1996, 2002), including several just to the north of Capanda (Ruas 1996). Bocage (1895) cited the species from Duque de Bragança, currently Kalandula, about 100 km NE of Capanda.

REPTILIA
CROCODYLIA
CROCODYLIDAE

Crocodylus niloticus Laurent, 1768

Material. 1 specimen: MNHNL/Rep/A/Croc 1

Comments. This juvenile specimen is referable to *C. niloticus,* which is widespread throughout much of sub-Saharan Africa. However, West African populations previously included within *C. niloticus* are now referred to a separate species, *C. suchus* Geoffroy St.-Hiliare, 1807 (Schmitz et al. 2003). The distribution of

Nile Crocodiles within Angola is poorly documented (Fergusson 2010), but the Kwanza River has long been regarded as having a large population (Hellmich 1957a). Ferreira (1903) cited the species as occurring at Duque de Bragança.

TESTUDINES
PELOMEDUSIDAE

Pelusios rhodesianus Hewitt, 1927
Material. 1 specimen (uncat. JC)
Comments. This specimen has the head coloration reported by Branch (2008) as typical of southern populations. The species is widely distributed in south-central Africa and there are numerous records from throughout Angola exclusive of the arid southwest (Broadley 1981; Iverson 1992; Broadley and Boycott 2008), including from the Kwanza River drainage.

Pelusios nanus Laurent, 1956
Material. 3 specimens: MNHNL/Rep/A/C 1, uncat. JC (2 specimens)
Comments. This species has a relatively limited distribution across central Angola, northern Zambia, and the southern Democratic Republic of Congo (Broadley 1981; Iverson 1992; Branch 2008; Vetter 2011). For Angola, the few available records are from Alto Chicapa (Lunda Norte province) in the northeast, and Calundo Lake and Cazombo (Moxico province) in the east (Laurent 1964). The Capanda records extend the known distribution by more than 100 km from previous records to the northeast, east, and south.

TESTUDINIDAE

Kinixys spekii Gray 1863
Material. 4 specimens: MNHNL/Rep/A/C 8, uncat. JC (3 specimens)
Comments. Capanda is near the northwestern extent of the distribution of this species, which has a broad range across savanna habitats of south-central Africa, including most of Angola (Broadley 1989; Iverson 1992; Branch 2008; Vetter 2011; Kindler et al. 2012). Specimens of *Kinixys belliana* Gray, 1831 reported by Bocage (1895) and Ferreira (1902) from approximately 100 km northeast in Kalandula (formerly Duque de Bragança) and by Laurent (1950) from Muita may also refer to this species.

SQUAMATA: LACERTILIA
AGAMIDAE

Agama cf. *congica* Peters, 1877
Material. 107 specimens: MNHNL/Rep/A/Ag 1–107
Comments. The identity of the large, colorful agamas of Angola has long been problematic and was discussed at length by Monard (1937) and Hellmich (1957a). Hellmich (1957a,b) referred *Agama agama* group specimens from northern Angola (Piri-Dembos, Cuanza Norte) to *A. agama agama* (Linnaeus, 1758). However, the distribution of this species remains poorly defined and has only been confirmed using genetics for populations north of Angola (Leaché et al. 2009; Mediannikov et al. 2012). Other agamas occurring in northern Angola are *A. planiceps schacki* Mertens, 1938, and the recently revalidated *Agama mucosoensis* Hellmich, 1957 (Wagner et al. 2012). Specimens from Capanda resemble *Agama congica*, a taxon currently placed in the synonymy of *A. agama*, but actually differing from that species on the basis of both coloration and scalation (P. Wagner, pers. comm.). Male nuptial color is an important character in distinguishing among *Agama agama* group species and female color is also species specific for the Angolan species (Wagner et al. 2012). Unfortunately, the Capanda specimens have darkened in preservative to the point that life color patterns cannot be discerned; specific identity could easily be verified by fresh material. *Agama mucosoensis* is common at Dondo, Mucoso, and Libolo/Luati (all in Cuanza Norte), at sites only 100 km downstream from Capanda (Hellmich 1957a, 1957b), as well as in the vicinity of Luanda (pers. obs.) and may also be expected in the region.

Acanthocercus cyanocephalus (Falk, 1925)
Material. 25 specimens: MNHNL/Rep/A/Ag 108–126
Comments. *Acanthocercus* species outside of Arabia and the Horn of Africa have long been referred to *Acanthocercus atricollis* (Smith, 1849), which Bocage (1866, 1895), Ferreira (1903), and Boulenger (1905) cited for Duque de Bragança (now Kalandula), about 100 km NE of Capanda. Boulenger (1905) recorded the species for Pungo Andongo, 20 km NE of Capanda. Klausewitz (1957) divided this species into several subspecies, but Angolan material fell into the nominotypical form. Subsequent revisionary work on the genus (Wagner et al., unpubl.) reveals that Angolan *Acanthocercus* are referable to *A. cyanocephalus*, a long-forgotten name proposed by Falk in 1925 based on Angolan material, but without a precise type locality. It occurs throughout most of western Angola, except in the arid southwest, as well as in portions of all neighboring countries. The species has been recorded (as *A. atricollis*) across the center and north of Angola (Boulenger 1905; Schmidt 1933; Monard 1937; Themido 1941; Laurent 1950, 1964; Manaças 1963).

CHAMAELEONIDAE

Chaemaeleo gracilis etiennei Schmidt, 1919
Material. 49 specimens: MNHNL/Rep/A/Ca 1–49
Comments. This subspecies of *C. gracilis* was recognized as distinct by Klaver and Böhme (1997) and Tilbury (2010). There are several records of *C. gracilis* for Angola, some of which represent this subspecies (Bocage 1895; Ferreira 1903; Parker 1936; Laurent 1964). Bocage (1895) and Ferreira (1903) cite *C. gracilis* for Duque de Bragança and Cazengo, but the closest previously published location is Pungo Andongo (Bocage 1895), 20 km northeast of Capanda. The subspecies *etiennei* has been recorded in the northeastern regions of the country by Laurent (1964), and for Pungo Andogo, Congulu, Duque de Bragança, Condo, Marimba, and Canhoca by Parker (1936). Capanda lies near the southwest border of the taxon's distribution. Hellmich (1957a, 1957b) recorded large series (as *C. gracilis*) from Piri-Dembos and Mucoso, Cuanza Norte. Tilbury (2010) plotted numerous localities in northern Angola.

GEKKONIDAE

Chondrodactylus pulitzerae (Schmidt, 1933)
Material. 2 specimens: MNHNL/REP/A/Gec 1–2
Comments. Both specimens were captured in January 2003. This species was originally described from southern Angola and long considered a synonym of *Pachydactylus* (now *Chondrodactylus*) *bibronii* (Smith, 1846). Benyr (1995) clarified the distinction between the more temperate *C. bibronii* and a more tropical *C. laevigatus*/*C. turneri* lineage and transferred *pulitzerae* to the synonymy of *Chondrodactylus laevigatus* (Benyr, 1995). Branch (1998) subsequently used the name *C. turneri* as a senior synonym of *C. laevigatus*, correcting Benyr's oversight of the former name's priority. Heinz (2011) demonstrated that *C. pulitzerae* is a distinct lineage, occurring in sympatry or at least parapatry with

C. turneri in extreme northern Namibia and southern Angola. Monard (1937) reported *Pachydactylus bibronii* from Kampulu and Humbi (Umbi) in Cuanza Sul and these appear to be the northernmost literature records, although Bocage (1895) reported them to be common south of the Kwanza in general. Most records for this species are in the southwest of Angola in Benguela province (Schmidt 1933; Parker 1936; Mertens 1938; Hellmich 1957a,b; Laurent 1964). The Capanda record reflects a northward range extension of approximately 160 km. This species has also been found at Cacuaco, 250 km WNW of Capanda (pers. obs.). It is probable that *C. pulitzerae* is widely distributed throughout the savanna biome of Angola, but perhaps occurs in low density in some areas, as is the case with *C. turneri* in eastern Africa.

Hemidactylus longicephalus Bocage, 1873
Material. 71 specimens: MNHNL/REP/A/Gec 3–71. MNHNL/REP/A/Gec 3–21 collected January 2003, MNHNL/REP/A/Gec 22–44 collected February 2003, MNHNL/REP/A/Gec 45–71 collected March 2003.
Comments. Despite a number of recent studies on the *Hemidactylus* of sub-Saharan Africa (Vences et al. 2004; Carranza and Arnold 2006; Miller et al. 2012), the status of many of the constituent taxa remains unsettled and the taxonomy of the group may be fairly characterized as among the most in need of revision of any geckos in the world. Capanda material appears to be referable to *H. longicephalus*, although the status of this taxon is itself unstable and several names that are currently placed in synonymy (e.g., Loveridge 1947) require further critical investigation. This species is widespread through Angola (Schmidt 1933; Laurent 1964) and into equatorial Africa (Loveridge 1947; Chirio and LeBreton 2007) and is broadly sympatric with the rather similar *Hemidactylus mabouia* (Moreau De Jonnès, 1818), throughout much of its range. Hellmich (1957b) reported on a large series of this species from Piri-Dembos (Cuanza Norte) and Manacas (1963) recorded it from Quizambil, Dande (Bengo Province) and Fazenda Otília, Encoge, and Quitexe (Uige Province). Bocage (1895) noted *Hemidactylus bocagii* Boulenger, 1892, currently considered a synonym of *H. longicephalus*, as occurring at Duque de Brangança and Pungo Andongo, approximately 100 and 20 km, respectively, northeast of Capanda.

GERRHOSAURIDAE

Gerrhosaurus nigrolineatus Hallowell, 1857
Material. 7 specimens: MNHNL/Rep/A/Ge 1–7
Comments. Bates et al. (2013) suggested that *G. nigrolineatus* was not monophyletic and resurrected *G. intermedius* Lönnberg, 1907 for eastern populations. Material from Angola is referable to *G. nigrolineatus sensu stricto*. This species is known from much of southern and central Africa and is widespread in Angola (Monard 1931, 1937; Laurent 1950, 1954; Hellmich 1957a; Manaças 1963), with the nearest location being in Duque de Brangaça, 100 km NE of Capanda (Bocage 1895). The Capanda specimens are from about 160 km SE of the type locality of *G. n. ahlfeldti* Hellmich and Schmelcher, 1956, currently regarded as a synonym of *G. n. nigrolineatus*, and about 100 km SW of the type locality of the taxonomically problematic *G. multilineatus* Bocage, 1866 (Haagner et al. 2000; Adolphs 2006).

SCINCIDAE

Trachylepis maculilabris (Gray, 1845)
Material. 36 specimens: MNHNL/Rep/A/Sc 1–36. MNHNL/REP/A/Sc 1–12 collected January 2003, MNHNL/REP/A/Sc 13–19 collected February 2003, MNHNL/REP/A/Sc 20–35 collected March 2003, MNHNL/REP/A/Sc 36 collected April 2003.
Comments. *Trachylepis maculilabris* has a wide distribution in sub-Saharan Africa as far south as Angola in the west (Trape et al. 2012). Mausfeld et al. (2004) noted that *T. maculilabris* may comprise at least two distinct species—one from West Africa representing the nominotypic *maculilabris*, and other from the East Africa. The Capanda material agrees entirely with the holotype of the species (see Appendix) and West African populations in general. Laurent (1950, 1954) recorded the species from several northern localities within Angola, including Dundo and Muita. Hellmich (1957a) reported it from Mucoso as well in south central Angola at Entre Rios, Bié Province and considered the species to be a human commensal. Bocage (1895) reported the species for Pungo Andongo, only 20 km NE of Capanda. Pungo Andongo is also the type locality of *Euprepes notabilis* Peters, 1879, currently considered as a synonym of *T. maculilabris*. The species has also been observed in human dwellings near Panguila swamp, near Kifangondo, 250 NW of Capanda (pers. obs.).

VARANIDAE

Varanus albigularis angolensis Schmidt, 1933
Material. Uncat JC (2 specimens)
Comments. Bayless (2002) summarized all known Angolan locality records for this taxon. Capanda lies near the northwest margin of the distribution of this subspecies and the species as a whole. It is replaced by *V. exanthematicus* to the north of the equatorial African forest belt. This species was discussed as *V. exanthematicus albigularis* by Monard (1937), Laurent (1954), and Hellmich (1957b).

Varanus niloticus (Linnaeus, 1758)
Material. 5 specimens: MNHNL/Rep/A/V 1–4, uncat JC (1 specimen)
Comments. Angolan material has been discussed by Monard (1937), Laurent (1950, 1954), Hellmich (1957a, b), and Manaças (1963). Bayless (2002) plotted the distribution of this species in Angola and throughout its range. The closest known occurrence lies 100 km NE of Capanda, in Kalandula, formerly Duque de Bragança (Bocage 1895).

SQUAMATA: SERPENTES

Philothamnus heterodermus (Hallowell, 1857)
Material. 1 specimen: MNHNL/Rep/A/0 4
Comments. This species was first recorded for Angola by Parker (1936) and reported from Piri-Dembos by Hellmich (1957b). Its distribution in Angola remains poorly known.

ELAPIDAE

Naja anchietae (Bocage, 1879)
Material. 1 specimen: MNHNL/Rep/A/0 5
Comments. Broadley (1995) regarded this taxon as a subspecies of *N. annulifera* Peters, 1854. Manaças (1982) provided a list of Angolan localities for this species. Known records are from southern Angola, as far north as 12°S (Broadley 1995; Broadley and Wüster 2004), thus the Capanda record represents a substantial northern extension of the species range.

Discussion

The species in this collection represent only a small portion of the expected fauna in this area (e.g., Bocage 1895; Monard 1937,

1938; Laurent 1964; Ruas 1996, 2002). Most of the species reported here are both easily caught and habitat generalists, and there is a notable absence of habitat specialists, such as fossorial species. In addition to the species recorded here, the unpublished list referred to above (see Materials and Methods above) cites 154 additional snake specimens from several taxa: *Elapsoidea semiannulata* Bocage, 1882, *Philothamnus* cf. *hoplogaster* (Günther, 1863), *Bitis arietans* (Merrem, 1820), *Naja nigricolis* (= *Naja nigricollis* Hallowell, 1857), *Telescopus semiannulatus* Smith, 1849, *Lamprophis fuliginosus* (= *Boaedon fuliginosus* (Boie, 1827)), *Naja melanoleuca* Hallowell, 1857, *Dendroaspis polylepis* Günther, 1864, *Python natalensis* Smith, 1840, *Dispholidus typus* (Smith, 1828), *Psammophis* sp. and *Philothamnus* sp. However, these identifications cannot be confirmed given that the associated specimens are no longer present in the collection. Other species noted in this same list but also missing from the collections are *Mabuya* cf. *sulcata* (= *Trachylepis sulcata* [Peters, 1867]), *Agama agama* (Linnaeus, 1758), *Mabuya varia* (= *Trachylepis varia* [Peters, 1867]), *Chamaeleo dilepis* Leach, 1819, *Chamaeleo gracilis* Hallowell, 1844, *Gerrhosaurus flavigularis* Wiegmann, 1828, *Kinixys belliana* Gray, 1831, and *Pelusios* cf. *subniger* (Lacépède, 1789). Some of these clearly represent synonyms or misidentifications, although without specimens their actual identities cannot be confirmed. Yet the collection remains interesting for its considerable numbers and for records of several species not previously known from this region of Angola. While a number of species were known from the region, several here represent important range extensions within Angola, such as *Pelusius nanus*, *Chondrodactylus pulitzerae*, and *Naja anchietae*, or even new records for the country, as may be the case for *Kassina maculosa*. Capanda is located in an interesting region where the boundaries of several different faunal communities meet. Many species more common in the southern regions of the country, such as *Kinixys spekii*, *Varanus albigularis angolensis*, *Chondrodactylus pulitzerae*, and *Naja anchietae* may reach their northern limits in Capanda. Similarly, Capanda represents the southern limit for other species such as *Kassina maculosa* and *Pelusios nanus*. The Capanda region is also close to the type localities of many amphibian and reptile species, especially those described by Franz Steindachner (1834–1919) and José Vicente Barbosa du Bocage (1823–1907) in the nineteenth century. For example, Duque de Bragança (100 km NE of Capanda) is the type locality for many amphibians and reptiles, including *Rana bragantina* Bocage, 1864 (now a synonym of *Hoplobatrachus occipitalis* [Günther 1858]), *Hyperolius angolensis* Steindachner, 1867, *Hyperolius bocagei* Steindachner, 1867, *Rana occipitalis* Bocage, 1866 (now a synonym of *Hoplobatrachus occipitalis* [Günther, 1858]), *Amietia angolensis* (Bocage, 1866), *Ptychadena subpunctata* (Bocage, 1866), *Hyperolius cinnamomeoventris* (Bocage, 1866), *Hyperolius steindachneri* Bocage, 1866, *Hyperolius fuscigula* Bocage, 1866, *Hyperolius tristis* Bocage, 1866 (now a synonym of *Hyperolius cinnamomeoventris* [Bocage, 1866]), *Hyperolius quinquevittatus* Bocage, 1866, and *Amietophrynus funereus* (Bocage, 1866), *Gerrhosaurus multilineatus* Bocage, 1866, *Sepsina angolensis* Bocage, 1866, *Afrotyphlops angolensis* (Bocage, 1866), *Philothamnus dorsalis* (Bocage, 1866), *Prosymna ambigua* (Bocage, 1873). Even this small survey of the Capanda collection at MNHN demonstrates how much remains to be discovered about Angola's biodiversity. Given its large size and diversity of habitat types, Angola remains among the most poorly studied pieces of the African zoogeographic puzzle. Further studies of historical collections within the country will contribute important details to understanding the distributions of Angolan amphibians and reptiles and thus facilitate conservation assessments and management.

Acknowledgments.—We thank the Angolan Ministry of Culture, particularly Rosa Cruz da Silva, and Francisco Costa (director of the International Exchange Office of the Ministry of Culture of Angola), for the authorization to study the collections of the Museu Nacional de História Natural. We also thank the biologists of the museum, Francisca Adelaide da Costa, Esteves Afonso, Rosa Pina, and Leonor Pedro, and to its technicians, Rui Francisco Mukila, Cláudio Marcolino, and Rosa Mendes Paulo for their help during the identification work. Cláudio Marcolino passed away after the final acceptance of this paper. For his help and vibrant dedication during our works in the Luanda Museum, we would like to dedicate this paper to his memory. We also want to thank the Methodist University of Angola, especially Teresa Silva Neto, Luis Sebastião, and Diogo Figueiredo for their support during our stay in Angola. This work has been partly funded by a US National Science Foundation grant to DCB and AMB (DEB 1202609 and 1019443).

NATURAL HISTORY NOTES

GYMNOPHIONA — CAECILIANS

***DERMOPHIS GLANDULOSUS* (San Isidro Caecilian). PREDATION.** Snakes are considered the main predators of caecilians (Duellman and Trueb 1994. Biology of Amphibians. Johns Hopkins University Press, Maryland. 670 pp.; Kupfer et al. 2003. Amphibia-Reptilia 24:212–215). Moreover, Pérez-Santos and Moreno (1988. Ofidios de Colombia. Museo Regionale di Scienze Naturali Torino, Monografia VI. 497 pp.) suggested that some species of coral snakes, such as *Micrurus nigrocinctus*, *M. spixii*, and *M. lemniscatus*, frequently include caecilians in their diets. At 1045 h on 24 July 2009, an adult *Micrurus multifasciatus* (Many-banded Coral Snake) was found preying upon a *Dermophis glandulosus* (MVUP 2307; total length = 331 mm). The observation took place on the trail to Cerro Brewster, located within the Parque Nacional Chagres, Panamá, Panamá (9.32053°N, 79.28876°W, datum WGS84; elev. ~800 m), which has vegetation typical of a submontane tropical forest. The *Micrurus multifasciatus* was photographed with the caecilian and released. The specimen of *D. glandulosus* showed signs of bites in the neck and nuchal region. This is the second record of predation on *D. glandulosus* by a coral snake (the first report was predation by *Micrurus alleni*; Arias and Chaves 2013. Herpetol. Rev. 44:657–658) and the first report of this species in the diet of *M. multifasciatus*.

We thank the Fundación Parque Nacional Chagres for providing funding for the fieldwork and the Autoridad Nacional del Ambiente for providing the appropriate permissions.

FIG. 1. *Micrurus multifasciatus* captured while preying upon *Dermophis gladulosus*.

CAUDATA — SALAMANDERS

***AMBYSTOMA VELASCI* (Plateau Tiger Salamander). PREDATION.** *Ambystoma velasci* is distributed in the Mexican states of Nuevo Leon on the east and Chihuahua on the west, southward to the Transvocanic Belt, and from Colima to Veracruz (Lemos-Espinal and Dixon 2013. Amphibians and Reptiles of San Luis Potosi. Eagle Mountain Publishing, Eagle Mountain, Utah. 300 pp.). At 1520 h on 26 April 2014, we observed a female *Thamnophis cyrtopsis* (Black-necked Gartersnake; SVL = 59. 2 cm, total length = 76.6 cm, mass = 115.5 g; body temperature = 29.0°C; UANL 7362) capturing, subduing, and consuming a neotenic *A. velasci* (Plateau Tiger Salamander; SVL = 8.89 cm, total length = 16.90 cm, mass = 44.03 g; UANL 7409; Fig. 1). The locality was San Jose de Gonzalez, Galeana, Nuevo Leon, Mexico (24.47847°N, 100.48846°W, datum WGS84; elev. 1846 m). This observation took place on land, very close to a permanent water body known as "Alijibes." The area is a microphyllous desert scrubland plant community. Although salamanders have been reported in the diet of *T. cyrtopsis* (Lemos-Espinal and Dixon 2013, *op. cit.*; Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. University of Oklahoma Press, Norman, Oklahoma. 332 pp.), to our knowledge this is the first record of *A. velasci* as prey of *T. cyrtopsis*.

FIG. 1. *Thamnophis cyrtopsis* consuming a neotenic *Ambystoma velasci*.

caguigon16@gmail.com), and **SERGIO ALBERTO LUNA-PEÑA** (e-mail: sergio.lunap@gmail.com), Universidad Autónoma de Nuevo León, Facultad de Ciencias Biológicas, Laboratorio de Herpetología, Apartado Postal #513, San Nicolás de los Garza, Nuevo León, C.P. 66450, México.

***EURCYEA BISLINEATA* (Northern Two-lined Salamander). LEUCISM.** Adult *Eurycea bislineata* are wide-ranging stream salamanders that are usually distinguishable by two dark dorsolateral lines bordering a broad yellowish mid-dorsal stripe (Conant and Collins 1998. A Field Guide to Reptiles and Amphibians of Eastern and Central North America, 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.). Amelanism, leucism, and albinism have been reported in other plethodontids, including *Plethodon cinereus* (Moore and Gilhen 2011. Can. Field Nat. 125:58–60; Russell et al. 2011. Can. Field Nat. 123:359–362), and larval *Eurycea cirrigera* (Miller and Braswell 2006. Herpetol. Rev. 37:198). However, to our knowledge leucism has not been reported in a wild adult *E. bislineata.*

On 12 July 2014, we collected a leucistic adult *E. bislineata* (SVL = 3.3 cm; Fig. 1) while conducting a survey for salamanders along a 30-m stream transect in Nathan Hale State Forest, Tolland Co., Connecticut, USA (41.76320833°N, 72.350525°W; datum WGS84). The individual exhibited extremely reduced pigmentation on the head and body, resulting in a translucent appearance. The tail retained some light yellow pigmentation, and the eyes were darkly pigmented. The individual was found under a rock on a mossy bank of a mostly dry first order stream. It was marked using a visible implant elastomer tag and released at the capture location according to the study protocol. Of 68 *E. bislineata* collected since sampling began 29 May 2014, this is the only abnormally colored individual detected.

We thank Tracy Rittenhouse for providing helpful comments.

FIG. 1. Leucistic adult *Eurycea bislineata* from Tolland Co., Connecticut, USA.

D. CRISTINA MACKLEM, Department of Ecology and Evolutionary Biology, University of Connecticut, Storrs, Connecticut, USA (e-mail: Diana.Macklem@uconn.edu); **JASON H. O'CONNOR**, Department of Natural Resources and the Environment, University of Connecticut, Storrs, Connecticut, USA.

***EURYCEA LONGICAUDA* (Long-tailed Salamander). HABITAT.** *Eurycea longicauda* are often found near water, such as pond edges or streams, but they are also known to make use of caves in many parts of their range (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 587 pp.). Surprisingly, there are relatively few observations on how *E. longicauda* use terrestrial habitat when they make moves away from water. Here I report observations of habitat use by *E. longicauda* when they are far from aquatic habitats. In particular, I use observations of their use of cover boards placed along an edge between a second-growth deciduous habitat and an abandoned pine plantation habitat to examine activity in deciduous, mixed coniferous-deciduous, and coniferous habitats.

I recorded *E. longicauda* use of coverboards (pine lumber; 30.5 × 61.0 cm, 4 cm thick) biweekly from late-March/early-April through late-October/early-November from 2003 to 2009. The study area consisted of a mixed mesophytic forest (dominant species = *Acer saccharum*) and an abandoned pine (*Pinus strobus*) plantation on the Denison University Biological Reserve, Granville, Licking Co., Ohio, USA (40.085367°N, 82.509422°W, datum WGS84; elev. 341 m), and is nearly 400 m from the nearest surface water. I classified cover board habitat type based on the proportion of the five closest trees that were deciduous or coniferous (see Grasser and Smith 2014. J. N. Am. Herpetol. 2014:53–58 for details).

I made a total of 44 observations on *E. longicauda* over the course of the study. Observations of *E. longicauda* were highest in June (13) and July (14), with lower numbers observed in May (9), August (6), and September (2), and I never observed *E. longicauda* in March, April, October, or November. I made the most observations of *E. longicauda* in the deciduous habitat (29), followed by the mixed habitat (11), and the coniferous habitat had the fewest observations (4). However, the distribution of observations of salamanders did not differ significantly from what would be expected based upon the number of cover boards in each habitat (χ^2 = 2.598, P = 0.273). Previous descriptions of habitat use by *E. longicauda* are usually relatively vague. For example, several studies refer to these salamanders being found under cover objects near ponds or streams (Martof 1955. Copeia 1955:166–170; Muchmore 1955. Ohio J. Sci. 55:267–270; Holman 1960. Copeia 1960:56–58; Anderson and Martino 1967. Herpetologica 23:105–108), on wooded slopes (Wicknick et al. 2005. Ohio J. Sci. 105:2–7), in forests (Anderson and Martino 1966, *op. cit.*), or in areas with vegetation (Gordon 1953. Tulane Stud. Zool. 1:55–60). My observations suggest that *E. longicauda* will use cover objects in a variety of wooded habitats at a distance from water.

I thank all of the many students who helped check the cover boards throughout this long-term study.

GEOFFREY R. SMITH, Department of Biology, Denison University, Granville, Ohio 43020, USA; e-mail: smithg@denison.edu.

***PLETHODON CHATTAHOOCHEE* (Chattahoochee Slimy Salamander). HABITAT.** *Plethodon chattahoochee* is a member of the slimy salamander (*P. glutinosus*) complex as delineated by Highton et al. (1989. Univ. Illinois Biol. Monogr. 57:1–78). It is native to the montane deciduous forests of north-central Georgia and extreme southeastern North Carolina. All members of this complex are normally found in moist forest-floor habitats, such as beneath rocks and logs (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, DC. 587 pp.), as well as in caves (Peck 1974. Nat. Speleol. Soc. Bull. 36:7–10), and underneath the bark of standing trees (Thigpen et al. 2010. Herpetol. Rev. 41:159–162). All species of

Plethodon have direct development and with few exceptions are not considered to be tied to aquatic habitats.

At 2030 h on 03 August 2014, we found an adult *P. chattahoochee* perched on top of a small rock in the middle of fast-flowing Mulky Creek in Chattahoochee National Forest, Union Co., Georgia, USA (34.783838°N, 84.055721°W; datum WGS84). The stream was ~5 m wide and ~20 cm deep. We encountered the same salamander twice more over the next 2 h as it moved among different rocks in the stream, seemingly following no particular pattern with respect to the banks or direction of flow of the stream. At no point did we observe it submerged, although it swam capably downstream using its tail for lateral undulation when we dislodged it from its perch. It is uncertain whether this salamander's presence in the stream was intentional or accidental, but it apparently was not actively trying to return to the shore. It is unusual for any member of the *P. glutinosus* complex to be found in such an aquatic habitat.

ANURA — FROGS

***AGALYCHNIS DACNICOLOR* (Mexican Leaf Treefrog). PREDATION.** *Agalychnis dacnicolor* is a medium-sized tree frog endemic to elevations less than 1000 m in the tropical deciduous forest of Mexico (Duellman 2001. The Hylid Frogs of Middle America, Expanded Edition. Society for the Study of Amphibians and Reptiles, Ithaca, New York, 753 pp.). Possible predators of *A. dacnicolor* include snakes of the genera *Leptophis*, *Drymobius* and *Leptodeira*; however these observations are not formally established in the scientific literature. At 2024 h on 16 November 2011, in the remnants of a temporary pool formed during the wet season (18.001963°N, 98.520717°W; datum WGS84), we discovered an adult male Mexican Blue-footed Tarantula (*Bonnetina papalutlensis*) with a newly metamorphosed *A. dacnicolor* in its chelicerae (Fig. 1). In the general area we also observed a large number of young frogs emerging from the same pool. Most frogs showed signs of a tail, suggesting that this was a recently metamorphosed cohort. This is the first record of predation on *A. dacnicolor* by an arthropod.

PHOTOGRAPH BY ERIC CENTENERO-ALCALA.

***ANAXYRUS DEBILIS* (Green Toad). PREDATION.** Little is known about the natural history of *Anaxyrus* (=*Bufo*) *debilis* except that it breeds in shallow temporary rain pools, fishless ponds, or intermittent streams coinciding with the onset of summer rains (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. University of New Mexico Press, Albuquerque. 431 pp.). Here I describe predation of *A. debilis* by the Great Horned Owl (*Bubo virginianus*).

On 28 June 2010, a dried carcass of an adult male (approx. SVL = 34 mm, possessing a black throat) *A. debilis* was found while collecting owl pellets under a small nesting cave of a pair of Great Horned Owls at Lake Alan Henry Wildlife Mitigation Area, ca. 13 km S, 26 km W of Clairemont, Kent Co., Texas, USA (33.048429°N, 101.033878°W; datum WGS84). The only visible injury was a wide gouge behind the eyes which incised the left parotoid gland. Based on the previous collection date of owl pellets and the amount of desiccation, the toad was probably preyed upon between 14–24 June 2010. Heavy rains occurred twice during the period, resulting in the filling of many depressions created by cattle and feral hogs, conducive to *A. debilis* breeding (Griffis-Kyle 2009. Herpetol. Rev. 40:199–200). The male *A. debilis* was probably preyed on while calling after the heavy rain, brought to the nestlings, then discarded, likely because its parotoid gland was punctured.

As an opportunistic predator, the Great Horned Owl feeds on a wide variety of nocturnal prey, primarily mammalian, with only a very small percentage of the diet comprising amphibians (Artuso et al. 2014. The Birds of North America Online: http://bna.birds.cornell.edu/bna/species/372). For North America, I found no previous records of the Great Horned Owl preying on any species of toad (Artuso et al. 2014, *op. cit.*) and only few records of owls preying on bufonids. The lack of bufonids in owl prey data and the incident reported herein are contrary to the statement of Olsen (1989. Copeia 1989:391–397) that owls are able to avoid dorsal surface toxins by consuming the vulnerable ventral portions.

STEPHEN KASPER, Lake Alan Henry Wildlife Mitigation Area, Parks and Recreation Department, City of Lubbock, Lubbock, Texas 79401, USA; e-mail: skasper@mail.ci.lubbock.tx.us.

***CTENOPHRYNE ATERRIMA* (Costa Rica Nelson Frog). DIET.** *Ctenophryne aterrima* is a secretive, fossorial, and nocturnal frog that spends much time under surface litter on the forest floor. This species is considered insectivorous, more or less exclusively eating termites and ants (Savage 2002. The Amphibians

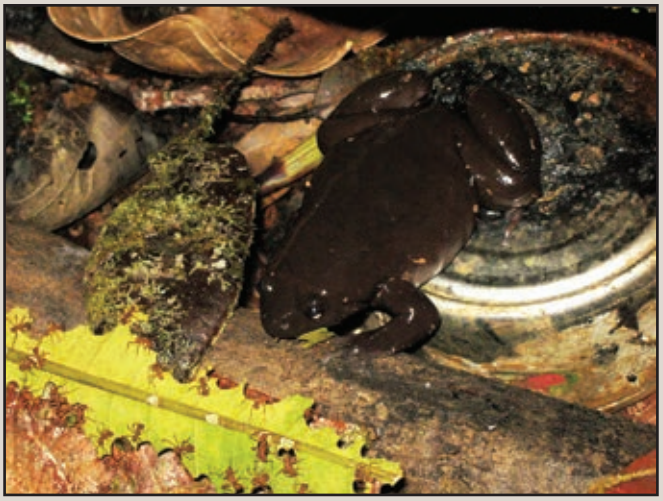

FIG. 1. *Ctenophryne aterrima* feeding on leafcutter ants (*Acromyrmex* sp.) in the cloud forest of Cerro Brewster, Chagres National Park, Panamá.

and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. The University of Chicago Press, Chicago, Illinois. 934 pp.). At 2216 h on 20 July 2009 in the Chagres National Park in Cerro Brewster, Panamá, Panamá (9.31995°N, 79.28871°W, datum WGS84; elev. 800 m), we found a *C. aterrima* preying on leafcutter ants (*Acromyrmex* sp.). This observation was made on a cloudy night (mean temp. = 22.7°C) in a cloud forest within a hole in the ground used for dumping waste. The frog sat on one side of the passing group of ants, observing their movements and employing a sit-and-wait feeding strategy. In a period of approximately ten minutes it only ate two ants and removed pieces of leaves from its mouth with its forelimbs. The frog and ants were photographed and left without disturbance. This is the first report of predation on leafcutter ants of genus *Acromyrmex* by *C. aterrima* in its natural distribution.

We thank the Fundación Parque Nacional Chagres for providing funding for the fieldwork, the Autoridad Nacional del Ambiente for providing the appropriate permissions and Ernesto Gómez for verification genus of ants.

ÁNGEL SOSA BARTUANO (e-mail: asosa2983@gmail.com), and **JORGE GUERREL** (e-mail: jguerrel@gmail.com), Sociedad Mastozoológica de Panamá, Apartado 0835-00680, Panamá, Republic of Panamá.

***ELEUTHERODACTYLUS WIGHTMANAE* (Melodious Coqui). REPRODUCTION, PARENTAL CARE, AND CALLING SITES.** *Eleutherodactylus wightmanae* is a small anuran (mean SVL = 20.2 mm) common in high elevation forests and inhabits forest leaf litter (Stewart and Woolbright 1996. *In* Reagan and Waide [eds.], The Food Web of a Tropical Rain Forest, pp. 273–320. The University of Chicago Press, Chicago, Illinois). The species is listed as endangered on the IUCN Red List (Angulo 2008. www.iucnredlist.org, Version 2014; accessed 26 September 2014); however, the Department of Natural and Environmental Resources of the Commonwealth of Puerto Rico does not list the species or consider it to be under any imminent threat (Departamento de Recursos Naturales y Ambientales. 2004. Reglamento para Regir las Especies Vulnerables y en Peligro de Extinción en el Estado Libre Asociado de Puerto Rico. Departamento de Estado Número Reglamento 6766. ELA, DRNA, San Juan, Puerto Rico. 60 pp.).

Male *E. wightmanae* call up to 100 cm above the ground but females rarely climb (Drewry and Rand 1983. Copeia 1983:941–953). Little is known of the reproductive biology of this species (Joglar 1998. Los Coquíes de Puerto Rico: Su Historia Natural y Conservación. Editorial de la Universidad de Puerto Rico, San

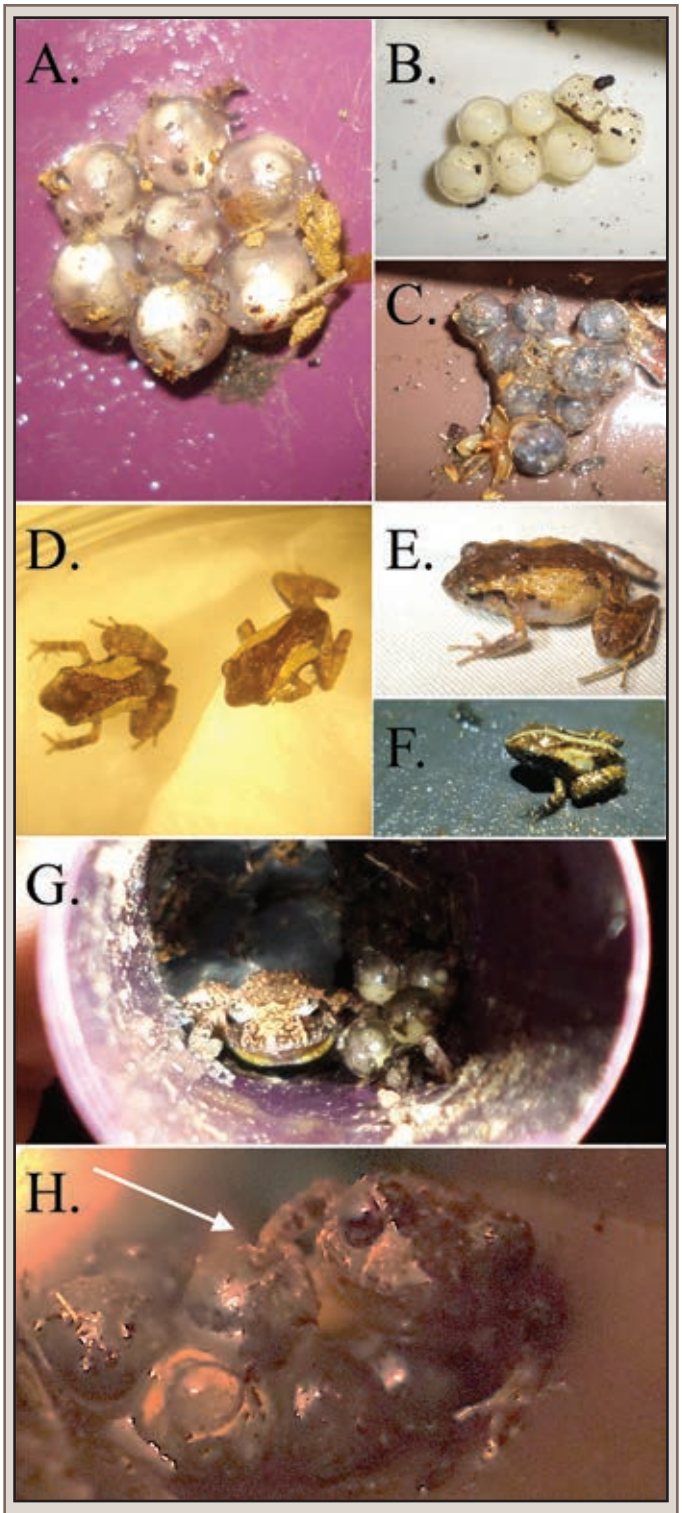

FIG. 1. *Eleutherodactylus wightmanae* in Puerto Rico. A–C) Shape and size characteristics of egg clutches in plastic tubes. D) dorsal coloration patterns in hatchlings in the laboratory. E) dorsal coloration pattern in an adult in the field. F) dorsal coloration pattern in a hatchling in the field. G–H) males guarding egg clutches inside plastic tubes (arrow in (H) highlights guarding male showing brooding behavior, with his fore limb in contact with an egg).

Juan. 232 pp.) and information on its egg clutches is limited to two observations: egg clutches having four and five eggs, one clutch having eggs with a mean diameter of 4.39 mm (N = 3 eggs); and both egg clutches being found inside curled leafs of *Cecropia peltata* or "yagrumo" (Joglar et al. 2005. Herpetol. Rev. 36:433–434). Anecdotal accounts refer to male parental care (Townsend 1996. *In* Powell and Henderson [eds.], Contributions to the West Indian Herpetology: A Tribute to Albert Schwartz, pp. 229–239. SSAR Contributions to Herpetology, Vol. 12, Ithaca, New York; Joglar et al. 2005, *op. cit.*). Herein, we provide data on egg clutch characteristics, parental care, and calling sites that expands our knowledge on the reproductive biology of the species.

This study was carried out between 31 August 2013 and 16 May 2014 in the rainforest of the Sierra de Cayey mountains (Cayey-Guayama municipalities) in southern Puerto Rico (18.054405°N, 66.123019°W, datum WGS84; elev. 817 m). The major vegetative cover (>50% of higher plants in the study area) consists of Sierra Palm (*Prestoea montana*). We placed 121 plastic tubes (diameter = 23.5 mm; length = 150–170 mm) 2 m apart from each other, in each of two 20 × 20 m plots (total tubes: 242) on the forest litter of the study area. The 20 × 20 m plots were approx. 200 m apart. The tubes were used by *E. wightmanae* as retreat and breeding sites and we collected data on clutch size, egg diameter, and clutch shape. Mean (± SD) number of eggs per clutch = 7.04 ± 1.85 (range: 4–11 eggs, N = 24 clutches); mean (± SD) egg diameter was 4.53 ± 0.65 mm (range: 4–5.8 mm, N = 15 eggs from N = 6 egg clutches). The most frequent shape of the egg mass was a radiating arrangement of six eggs around a center egg, all deposited in a single layer (Fig. 1A). Other shapes include an elongated egg mass and eggs spread in a larger non-geometric design (Fig. 1B–C). Basic dorsal coloration patterns for N = 22 adults (in decreasing order of abundance) were: no obvious dorsal pattern (N = 9), reversed comma (N = 7), reversed comma and light mid-dorsal line on a darker background (N = 3), dark inter orbital band on a lighter background (N = 2), light colored snout region on a darker background (N = 1). Likewise, for N = 18 hatchlings from four egg clutches: no obvious dorsal pattern (N = 11), reversed comma (N = 6), and reversed comma and light mid-dorsal band (N = 1). When patterned, recently hatched juveniles had similar coloration and the reversed comma pattern typically found in adults (Fig. 1D–E). On one occasion, however, we found a recently hatched juvenile with the pattern described above along with a mid-dorsal stripe on a darker background (Fig. 1F) which has not been observed in adults so far. Parental care, which is performed only by the male, was observed in seven of the 24 egg clutches (Fig. 1G–H) found during daytime hours (1500–1730 h). Data on calling males were collected between 1859 h and 2115 h during the sampling period. Calling males (N = 28) were found on vegetation at heights between 0.0 m and 0.5 m above the ground (mean ± SD = 0.25 ± 0.14 m). Calling males were found on surfaces that included (in decreasing order of abundance): leaves of short woody plants (8); dry leaflets of *P. montana* leaves on the ground (5); dry sheaths of *P. montana* leaves on the ground (4); fronds of ferns (4); leaf blades of herbaceous plants (3 on Poaceae, also known as Gramineae); tree trunks (2); inside curled dry sheaths of *P. montana* leaves on the ground (1); and leaves of seedlings of *P. montana* (1).

Puerto Rico has two main seasons: a warmer rainy period (approx. from May to late December) and a cooler dry period (approx. from January to April). Between 31 August 2013 and 14 December 2013 we found eight egg clutches (total = 57 eggs), while between 16 January 2014 and 14 April 2014 we found five egg clutches (total = 29 eggs). In only one visit in 16 May 2014 (a month that marks the beginning of the warmer and rainy period) we found 11 egg clutches (total = 83 eggs). The large number of egg clutches recovered in May suggest that peak breeding in this species may coincide with the onset of the warm, rainy season. Therefore, egg clutch production by *E. wightmanae* may follow a seasonal pattern similar to that in other Puerto Rican *Eleutherodactylus* with the exception of the ground-dwelling Puerto Rican Dwarf Coqui, *E. unicolor*, which shows the opposite pattern (reviewed by Joglar 1998, *op. cit.*).

Extensive surveys conducted by our research team since May 2014 in forested mountain areas (>13 sites) throughout Puerto Rico revealed that the species is abundant and frequently found at every site. However, repeated visits to a single site revealed substantial variation in calling intensity for this species, which may lead to false absences if acoustic surveys are not conducted on successive nights at each site.

We thank E. Agosto-Torres, Ashley Bernardi-Salinas, Sheila M. De León-Santiago, Y. M. Flores-Rodríguez, Rayza M. Hernández-Muñíz, Tessaliz Quiles-Delgado, Coralys Vicéns-López, and Shayna Zema for their field assistance.

***HYLA ARENICOLOR* (Canyon Treefrog). FEEDING ATTEMPT.** Most species of tree frogs consume primarily invertebrates. *Hyla arenicolor* is known to feed on arthropods, mainly insects (Abbadié-Bisogno 2004. Unpubl. thesis. FES, Iztacala; Winter et al. 2007. Herpetol. Rev. 38:323). The predation of lizards by hylid frogs has been previously documented, including lizards of the genus *Anolis* (Campbell 2007. Herpetol. Rev. 38:440; Preston 2010. Herpetol. Rev. 41:199). To our knowledge this is the first account of a predation attempt by *H. arenicolor* on *Anolis nebulosus* (Clouded Anole). At 1711 h on 04 December 2013, at Municipality of Valparaiso, Zacatecas, México (22.664482°N, 103.609491°W, datum WGS84; elev. 1874 m) an adult *H. arenicolor* was found trying to swallow an *A. nebulosus* of similar size. After a few minutes the lizard was regurgitated, possibly because it was too large (Fig. 1).

FIG. 1. Adult *Hyla arenicolor* attempting to eat a similar-sized *Anolis nebulosus*.

CARBAJAL-MÁRQUEZ**, Centro de Investigaciones Biológicas del Noroeste, Instituto Politécnico Nacional No.195 Col. Playa Palo de Santa Rita Sur, C. P. 23096, La Paz, Baja California Sur, México (e-mail: redman031@hotmail.com).

***HYPSIBOAS BOANS* (Giant Gladiator Treefrog). PREDATION.** *Leptophis ahaetulla* is primarily a diurnal and semiarboreal colubrid that inhabits forest, and forages primarily on the ground and in fallen vegetation, where its prey items are likely to be found at rest (Fraga et al. 2013. Guide to the Snakes of the Manaus Region, Central Amazonia. Manaus, Editora INPA. 303 pp.). The diet consists mostly of frogs, lizards, and birds, with dietary preference for hylids, especially those of the genus *Scinax* (Albuquerque et al. 2007. J. Nat. Hist. 41:1237–1243).

At 1417 h on 30 July 2011, we observed an adult *L. ahaetulla* preying upon an adult *Hypsiboas boans*. This event occurred at Reserva Biológica do Parazinho (00.875°N, 49.9875°W; datum WGS84), a fluvial island and part of the Islands of Bailique in the municipality of Macapá, and of the Amazon River basin. The snake attacked the hylid with a bite on the head region (Fig. 1). The predation event took 37 min., and the snake took 14 min. to swallow its prey. *Leptophis ahaetulla* is considered diurnal and semi-arboreal, while *H. boans* is nocturnal and arboreal (Lima et al. 2012. Guide to the Frogs of Reserva Adolpho Ducke, Central Amazonia. Manaus, Editora INPA. 168 pp.), suggesting that *L. ahaetulla* may capture *H. boans* during the day when the frogs are inactive.

FIG. 1. *Leptophis ahaetulla* trying to swallow a *Hypsiboas boans* in Reserva Biológica do Parazinho, municipality of Macapá, North Brazil.

COSTA-CAMPOS**, Universidade Federal do Amapá, Departamento de Ciências Biológicas e da Saúde, Laboratório de Herpetologia, Campus Marco Zero, 68903-419, Macapá, AP, Brazil (e-mail: eduardocampos@unifap.br).

***LEPTOBRACHIUM HENDRICKSONI* (Spotted Litter Frog). DEATH FEIGNING.** Amphibians are common prey items for a wide range of predators. To escape predation they employ various defensive behaviors such as death feigning, stiff-leggedness, lung inflation, mouth gaping, and body raising (Toledo et al. 2011. Ethol. Ecol. Evol. 23:1–25). *Leptobrachium hendricksoni* is known from Malaysia, Thailand, and Indonesia where it occurs in forest leaf litter, primarily at low altitudes of primary and secondary forests (Berry 1975. The Amphibian Fauna of Peninsular Malaysia. Tropical Press, Kuala Lumpur. 133 pp.; Ibrahim et al. 2008. The Common Amphibians and Reptiles of Penang Island. The Forestry Department of Penang, Malaysia. 116 pp.). Herein we report for the first time death feigning (thanatosis) behavior of this species as a way to avoid predation.

At ~2130 h on 22 November 2013, an adult *L. hendricksoni* (Fig. 1A) was captured while hiding among leaf litter near a tree buttress at Ulu Paip Receational Forest, Kedah, Malaysia (5.242212°N, 100.400635°E, datum WGS84; elev. < 200 m). The specimen was brought back to the laboratory and measured (SVL = 46.25 mm, head width = 21.37 mm, mass = 9 g). When approached for photographs, this specimen exhibited death-feigning behavior. It suddenly turned its belly up, inflated the body, and exposed its ventral surface (Fig. 1B). The frog remained in this motionless position with its eyes open for about 2–3 minutes. It then turned slowly back to its normal position and crawled under dead leaves to hide. The specimen was subsequently deposited at the School of Pharmacy, Universiti Sains Malaysia (13USM-UP-LH01).

I express my heartfelt gratitude to Universiti Sains Malaysia, Penang for all the facilities and amenities provided. This project was funded by USM, Short Term Grant no. 304/PFARMASI/6312127.

FIG. 1. An adult *Leptobrachium hendricksoni* from Kedah, Malaysia. A) Normal posture. B) Death feigning behavior.

SHAHRIZA SHAHRUDIN, School of Pharmaceutical Sciences, Universiti Sains Malaysia, 11800 Penang, Malaysia; e-mail: shahriza20@yahoo.com.

***LEPTODACTYLUS LATRANS* (Criolla Frog). PREDATION.** *Leptodactylus latrans* is a large anuran that inhabits swamps and streams with lots of vegetation, mostly wet grassland. Its distribution includes central Argentina, southern Brazil, Uruguay, and some parts of Paraguay (Cei 1980. Amphibians of Argentina. Ital. J. Zool., N. S. Monogr. 2, 609 pp.; Gallardo 1987. Anfibios Argentinos: Guía para su Identificación. Biblioteca Mosaico, Buenos Aires. 98 pp.). Tadpoles are gregarious and the female parent remains with the tadpoles until metamorphosis (Vaz Ferreira and Gehrau 1974. Rev. Biol. Uruguay 2:59–62; Vaz-Ferreira and Gehrau 1975. Phys. 34:1–14). *Astyanax eigenmanniorum* is a small fish (85 mm) that inhabits vegetated streams, calm rivers, ponds, and lakes from southern Brazil to central northern Argentina (Acosta et al. 2013. ProBiota, Ser. Tec. y Didac. 19:1–10). It is an omnivorous species, but its diet changes with the season. Its diet includes fish, eggs of the fish *Odontesthes bonariensis*, crustaceans, insects (larvae and adults), Coleoptera, Hymenoptera, spiders, and vegetation (Grosman 1999. Acta Sci. Biol. Sci. 21:267–275; Bennemann et al. 2005. Iheringia Ser. Zool. 95:247–254).

At 1500 h on 21 December 2013 at La Majadita (30.426°S, 67.2942°W, datum WGS84; elev. 979 m), Departamento Valle Fértil, San Juan, within the Parque Provincial Natural Valle Fértil, we observed a female *L. latrans* near a school of tadpoles. The frog was located in the water near the shore of a slow, permanent stream (25 cm deep). The tadpoles were at Gosner stage 20–23. When we came closer in order to obtain a photographic record, the female left the area, leaving the tadpoles alone. Immediately, a group (10–15 individuals) of *A. eigenmanniorum* began to feed on the colony of tadpoles. Fish approached the tadpoles until they were close enough to attack them. This action was conducted from the center to the shore of the stream, perpendicular to the direction of the water. Throughout our observations the female frog did not return to the tadpoles. We did not count how many tadpoles were eaten, but some were still alive when we left the site. This report represents a new prey species for *A. eigenmaniorum* and a new predator of *L. latrans* tadpoles.

MELINA JESÚS RODRÍGUEZ (e-mail: melina.rodriguez26@gmail.com), **TOMÁS AGUSTÍN MARTÍNEZ**, and **JUAN CARLOS ACOSTA**, Departamento de Biología, Facultad de Ciencias Exactas Físicas y Naturales, Universidad Nacional de San Juan. Av. José Ignacio de la Roza 590 (Oeste) Rivadavia, San Juan, Argentina.

***LITHOBATES AREOLATUS* (Crawfish Frog). PREDATION.** *Lithobates areolatus* is declining and distributed sparsely in remnant prairie habitats of the central United States (Parris and Redmer 2005. *In* Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 526–528. Univ. California Press, Berkeley). Owing to their extensive use of crayfish/small mammal burrows and highly secretive nature, limited data exist regarding the life history of *L. areolatus*, particularly natural sources of mortality. Experimentally, two species of insect (both backswimmers [*Notonecta* spp.]) have been identified as predators of larval *L. areolatus* (Cronin and Travis 1986. Herpetologica 42:171–174). Reported predators of post-metamorphic *L. areolatus* include *Heterodon platirhinos* (Eastern Hog-nosed Snake; Engbrecht and Heemeyer 2010. Herpetol. Rev. 41:168–170), *Coluber constrictor* (North American Racer; Engbrecht et al. 2012. Herpetol. Rev. 43:323–324), *Thamnophis sirtalis* (Common Gartersnake; Heemeyer 2011. Unpubl. MS Thesis. Indiana State University), and *Procyon lotor* (Raccoon; Engbrecht et al. 2012. Herpetol. Rev. 41:475); however, other common predators of ranid frogs such as snakes, birds, and mammals are suspected. Here we report the predation of *L. areolatus* by *Nerodia erythrogaster* (Plain-bellied Watersnake) and *Lanius ludovicianus* (Loggerhead Shrike) in northwest Arkansas, USA.

FIG. 1. Adult female *Nerodia erythrogaster* that regurgitated an adult *Lithobates areolatus* in Washington Co., Arkansas, USA.

FIG. 2. Juvenile *Lithobates areolatus* impaled on a barbed-wire fence by a *Lanius ludovicianus* (Loggerhead Shrike) in Benton Co., Arkansas, USA.

At 1500 h on 4 April 2014 we hand-captured a large adult female *N. erythrogaster* (SVL = 91.8 cm; 541.7 g) that was basking on emergent vegetation at Woolsey Wet Prairie Sanctuary (WWPS), Washington Co., Arkansas, USA (36.067175°N, 94.233639°W; datum WGS84). WWPS is a recently (2006) restored section of remnant prairie, perforated with numerous ephemeral wetlands which are known breeding sites for a population of *L. areolatus*. Upon capture, the *N. erythrogaster* voluntarily regurgitated an adult *L. areolatus* (Fig. 1; SVL = 8.0 cm, 24.55 g). A second well-digested *L. areolatus* was later recovered from the snake's stomach by palpation. On 10 April 2014, a second adult female *N. erythrogaster* (SVL = 75.8 cm; 321 g) was hand captured at WWPS that also regurgitated a single partially digested adult *L. areolatus*. *Nerodia erythrogaster* are thought to feed more heavily on amphibians than other species of *Nerodia* (Gibbons and Dorcas 2004. North American Watersnakes: A Natural History. University of Oklahoma Press, Norman. 438 pp.). Among 62 *N. erythrogaster* captured at WWPS between 15 March 2014 and 10 June 2014, 11 had palpable food items; of these, 100%

regurgitated anurans (*L. areolatus* [N = 2]; *L. sphenocephalus* [Southern Leopard Frog; N = 5]; *L. catesbeianus* [American Bullfrog; N = 3]; *Hyla versicolor* [Gray Treefrog]; N = 1). Although ranid frogs are important prey for *N. erythrogaster* at this site, *L. areolatus* exhibit a relatively short, early spring breeding season, and thus are likely only available for a limited time within the aquatic habitat.

An additional predation event involving a *L. ludovicianus* (Loggerhead Shrike) took place near Maysville, Benton Co., Arkansas, USA (36.406867°N, 94.568393°W; datum WGS84). Because shrikes lack large talons for shredding, they impale prey upon thorns or barbed-wire fences to aid in tearing and consuming. The diet of *L. ludovicianus* is composed primarily of insects (orthopterans, coleopterans), but may also include vertebrate prey (snakes, lizards, amphibians, small rodents, and birds), especially in winter months when invertebrates are a less reliable food source. After observing two *L. ludovicianus* on 6 July 2013, JCN discovered a juvenile *L. areolatus* hanging from a nearby barbed-wire fence (Fig. 2). These observations expand the known predators and sources of natural mortality for *L. areolatus* and support the contention that breeding and post-metamorphic migration present a period of heightened vulnerability for this species (Heemeyer and Lannoo 2012. Copeia 2012[3]:440–450).

We thank the city of Fayetteville and Woolsey Wet Prairie Sanctuary, especially Bruce Shackleford and Jeff Hickle, for site access and support. Funding was provided by the University of Arkansas and the Arkansas Audubon Society.

JOSEPH A. BAECHER (e-mail: jbaecher@gmail.com), **PHILIP N. VOGRINC**, **JACQUELYN C. GUZY**, **JOSEPH C. NEAL**, and **JOHN D. WILLSON** (e-mail: jwillson@uark.edu), Department of Biological Sciences, University of Arkansas, Fayetteville, Arkansas 72701, USA.

LITHOBATES JOHNI **(Moore's Frog). DIET.** *Lithobates johni* is a poorly-known frog endemic to the southeastern Sierra Madre Oriental of México. The original species description (Blair 1947. Am. Mus. Novit. 1353:1–17) reported spiders, crayfish, and eight insect orders in the diet of 22 dissected *L. johni*, suggesting that it is a generalist consumer of invertebrates. Here, we provide the first record of a vertebrate in the diet of *L. johni*, from a population in the state of Veracruz, México. At 0830 h on 15 January 2014, we observed an adult *L. johni* devouring an adult *Ecnomiohyla miotympanum* (Small-eared Treefrog) in the Reserva Ecológica del Río Pancho Poza, at 2040 m in Municipio de Altotonga (19.73989°N, 97.25072°W; datum WGS84). This reserve is a ca. 57-ha state-protected area, located on the southwestern outskirts of the town of Altotonga. Habitat is mesic cloud forest, transitioning into disturbed vegetation along the shoreline of the river where the frogs were observed. At this site, *R. johni* occurs at high density; between 10 and 20 individuals were seen along a 0.75-km stretch of the river that same day.

KARLO ANTONIO SOTO HUERTA, Rescatando Pancho Poza y su Biodiversidad A. C., Dr. Marin N° 2, Colonia Centro, Apartado Postal 93700, Altotonga, Veracruz, México; **MIGUEL ÁNGEL ENRÍQUEZ PITA**, Francisco y Madero N° 5, Colonia Centro, Apartado Postal 93700, Altotonga, Veracruz, México; **ADAM G. CLAUSE**, Warnell School of Forestry and Natural Resources, University of Georgia, 180 East Green Street, Athens, Georgia 30602, USA (e-mail: adamclause@gmail.com).

LITHOBATES SPHENOCEPHALUS **(Southern Leopard Frog). DIET.** *Lithobates sphenocephalus* have been reported to feed indiscriminately on a wide variety of insects, arthropods, snails, crayfish, fish, salamanders, and other anurans (Dodd 2013. Frogs of the United States and Canada. Vol. II. John Hopkins University Press. Baltimore, Maryland. 982 pp.). While not unexpected, this is the first record known to us of *L. sphenocephalus* consuming a lizard. At 0024 h on 04 April 2014, a *L. sphenocephalus* was found DOR on Zimmerscheidt Road, 13 km NNE of Columbus, Colorado Co., Texas, USA (29.81751°N, 96.50888°W, datum WGS84; elev. 85 m). The frog carcass contained a *Scincella lateralis* (Ground Skink). The anterior end of the *S. lateralis* was partially digested, and the posterior half of the lizard including the hind legs (tail missing) was largely intact and clearly recognizable. The specimens were deposited at the Texas Natural History Collection (TNHC 90500) and photographic vouchers deposited in the University of Arlington Digital Collection (UTADC-8113, UTADC-8114).

WILLIAM L. FARR (e-mail: williamfarr@sbcglobal.net), and **MICHAEL R. J. FORSTNER**, Texas State University, Department of Biology, 601 University Drive, San Marcos, Texas 78666, USA (e-mail: mf@txstate.edu).

PHYSALAEMUS CUVIERI **(Barker Frog). PREDATION.** *Physalaemus cuvieri* is a small leptodactylid species that is widely distributed in South America (Maffei and Ubaid 2014. Amphibians of Rio Claro Farm. Lençóis Paulista, São Paulo, Brazil. 123 pp.). *Philodryas nattereri* (Paraguay Green Racer) is a generalist predator, feeding on reptiles, but also mammals and amphibians (Mesquita et al. 2011. Herpetol. J. 21:193–198). At 1933 h on 27 November 2013, we observed a medium-sized adult *P. nattereri* feeding on a *P. cuvieri* male (Fig. 1) on the banks of a permanent pond, in Bonfinópolis municipality, Goiás, Brazil (16.5993°S, 48.8753°W, datum SAD69; elev. 919 m). The air temperature at the site was 23.5°C, water temperature was 29.3°C, and humidity was 81%. While we recorded the advertisement calls of the individual of *P. cuvieri* the snake captured it by the head. The *P. cuvieri* remained alive with an inflated body while being swallowed. The predation event lasted 7 min. To our knowledge this is the first record of predation of *P. cuvieri* by *P. nattereri*.

***RAORCHESTES BOMBAYENSIS* (Bombay Bush Frog) and *MICROHYLA ORNATA* (Ornate Narrow Mouthed Frog). INTERSPECIES AMPLEXUS.** When the breeding season of two or more anuran species overlaps spatiotemporally, amplexus between two different species may occur (Hobel 2005. Herpetol. Rev. 36:55–56). Herein we describe the unusual interspecies amplexus between a *Raorchestes bombayensis* male and a *Microhyla ornata* female (Fig. 1). *Raorchestes bombayensis* is endemic to the Western Ghats (elev. 400–1300 m) in the states of Maharashtra and Karnataka, India (Daniels 2005. Amphibians of Peninsular India. Indian Academy of Science and University Press, Hyderabad, India. 260 pp.). This species has direct development, breeds arboreally, and lays its eggs on leaves (Bossuyt et al 2001. Herpetol. Rev. 32:34–35). *Microhyla ornata* is a widespread species in South Asia occurring in lowland shrub forest, grassland and urban areas. It breeds in ephemeral and permanent water bodies and also in modified areas such as agricultural land. At 0126 h on 6 July 2014 we heard a chorus of males of *Microhyla* and *Zakerana* species from roadside water pools. We found more than 23 pairs of *M. ornata* in amplexus, and one case of a *R. bombayensis* male amplexing a female *M. ornata*. These observations took place in a village (Shelap) inside the Radhanagari Wildlife Sanctuary, Kolhapur, Maharashtra, India (16.4894°N, 73.9372°E, datum WGS84; elev. ca. 752 m).

Fig. 1. Amplexus of a *Microhyla ornata* female by a *Raorchestes bombayensis* male.

***RHINELLA CRUCIFER* (Striped Toad) AND *RHINELLA JIMI* (Cururu Toad). HETEROSPECIFIC AMPLEXUS.** Males of many bufonids are not very selective in their choice of mates, and may clasp other anuran species (e.g., Grogan and Grogan Jr. 2011. Herpetol. Rev. 42:89–90; Machado and Bernarde 2011. Herpetol. Notes 4:167–169), dead conspecifics (Ayres 2010. Herpetol. Rev. 41:192–193; Brito et al. 2012. North-West J. Zool. 8:365–366), and even inanimate objects (Streicher 2008. Herpetol. Rev. 39:75). Here we present the first reported case of heterospecific amplexus involving the neotropical bufonids *Rhinella crucifer* and *R. jimi*.

Fig. 1. Amplexus between male *Rhinella crucifer* and female *Rhinella jimi*.

On 18 July 2010, one of us (RLT) observed and photographed a male *R. crucifer* in amplexus with a much larger female *R. jimi* (Fig. 1) near a creek in the municipality of Ipiaú, state of Bahia, northeastern Brazil (14.0369°S, 39.6631°W, datum WGS84; elev. 160 m). The individuals were not captured. Hybridization between *R. icterica* and *R. ornata* (= *Bufo crucifer*; see Pombal and Haddad 2007, *op. cit.*) has been reported to create aberrant and unviable individuals (Haddad et al. 1990, *op. cit.*). Our report, like that of Haddad et al. (*op. cit.*), concerns one species of the *R. crucifer* group and one of the *R. marina* group, which raises the possibility that the progeny resulting from such a pairing may not be viable.

ROGÉRIO L. TEIXEIRA, Museu de Biologia Prof. Mello Leitão, Av. José Ruschi 4, Centro, 29650-000, Santa Teresa, ES, Brazil (e-mail: rogerioanfibio@yahoo.com.br); **RODRIGO B. FERREIRA**, Department of Wildland Resources and Ecology Center, Utah State University, Logan, Utah 84322-5230, USA (e-mail: rodrigoecologia@gmail.com); **DAVOR VRCIBRADIC**, Departamento de Zoologia, Universidade Federal do Estado do Rio de Janeiro, Av. Pasteur 458, Urca, 22240-290, Rio de Janeiro, RJ, Brazil (e-mail: davor@centroin.com.br).

***RHINELLA MAGNUSSONI*. BREEDING SITE.** The small bufonids of the *Rhinella margaritifera* group are known to use small temporary ponds as breeding sites, with the exception of *Rhinella castaneotica*, which reproduce in rainwater present inside the fallen fruit capsules of Brazilian Nut Tree (*Bertholletia excelsa*) opened by agoutis (*Cuniculus paca*, *Dasyprocta croconota*). Other amphibian species such as *Adelphobates castaneoticus* and *A. quinquevittatus* are also known to utilize these breeding sites.

On 04 December 2012 at 1236 h and 1921 h, in Amazon National Park, Pará, Brazil, (4.66452°S, 56.61645°W, datum WGS84; elev. 64 m; and 4.66595°S, 56.61757°W, datum WGS84; elev. 60 m, respectively), three amplectant pairs of the recently described *Rhinella magnussoni* were found inside the water of empty fruit capsules of Brazilian Nut Tree, and two of these capsules contained egg clutches (Fig. 1). This species is sympatric with the morphologically similar *R. castaneotica*, requiring a detailed examination of individuals to determine the species. We identified

PHOTO BY LUIS STORTI

FIG. 1. Amplectant pair of *Rhinella magnussoni* with their egg clutch inside a fruit capsule of the Brazilian Nut Tree (*Bertholletia excelsa*).

the specimens of *R. magnussoni* by the greater abundance of spiculated tubercles along dorsum and parotoid glands, as well as a more rounded snout in lateral view. This reproductive behavior is previously known only for *R. castaneotica* (Caldwell 1991. Pap. Avul. Zool. 37:389–400) and was not reported for *R. magnussoni* in the original description (Lima et al. 2007. Zootaxa 1663:1–15). This reproductive behavior may be more important for these small bufonids in the Amazon than previously acknowledged, indicating the importance of maintaining this ecological process through conservation of the multiple species involved, like *R. magnussoni*, *R. castaneotica*, *B. excelsa*, *C. paca*, and *D. croconota*.

***RHINELLA SCITULA* (Cope's Toad). PREDATION.** Fish are considered major predators of amphibian larvae in aquatic environments (Petranka et al. 1983. Copeia. 1983:624–628; Hecnar and M'Closkey 1997. Biol. Conserv. 79:123–131). However, the vast majority of the reports of vertebrates preying on adult amphibians are about reptiles, with few fish species reported (Toledo et al. 2007. J. Zool. 271:170–177). *Rhinella scitula* is a toad species that occurs primarily on well-preserved riparian forests at the southwest of Mato Grosso do Sul state, and is the most abundant anuran on Serra da Bodoquena Plateau (Uetanabaro et al. 2007. Biota Neotrop. 7:279–289). Nevertheless, there are no reports of predation in this species.

Remnants of an adult *R. scitula*, such as the head, skin, ribs, and femurs, were found in the guts of two *Rhamdia quelen* (Silver Catfish) individuals that were captured on 27 October 2006 within Salobrinha stream (20.6852°S, 56.7788°W; datum WGS84). The toad remnants were photographed and deposited in the Coleção Zoológica de Referência da Universidade Federal de Mato Grosso do Sul (ZUFMS-IMG 0015), as were the two individuals of *R. quelen* (ZUFMS-PIS 3956). *Rhamdia quelen* is an omnivorous, nocturnal catfish whose natural range covers the whole neotropical region. Despite the well-known opportunistic feeding behavior of this catfish (Gomes et al. 2000. Cienc. Rural 30:179–185; Casatti 2002. Biota Neotrop. 2:1–14), this is the first published evidence that they prey upon anurans.

The identification of the toad was provided by Franco Leandro de Souza (Universidade Federal de Mato Grosso do Sul).

SUGAI**, Laboratório de Ecologia, Universidade Federal de Mato Grosso do Sul, Cidade Universitária, CEP 79070-900, Campo Grande, MS, Brazil (e-mail: jlmassao@gmail.com).

***THELODERMA TRUONGSONENSE* (Truongson Bubble-nest Frog). FOOT-FLAGGING BEHAVIOR.** At 2200 h on 01 June 2011 following heavy rains during the day, a *Theloderma truongsonense* was observed perched approx. 1 m above the ground on a fern along a forest trail through primary forest in a basin laced with creeks at the south end of the Annamite Cordillera, ca. 6.43 km S of the village of Lang Vo, Quang Ngai Province, central Vietnam (14.61502°N, 108.61502°E, datum WGS84; elev. 931 m). The frog was not calling and no other frogs were observed nearby. It was observed to raise and extend its left rear leg, spread its toes, and rotate the extended limb in a wide circular motion (Fig. 1). It repeated this motion a few seconds later. Foot flagging is a visual territorial display used by some frogs in environments where auditory signals would be drowned out by background noise (Richards and James 1992. Mem. Queensland Mus. 32:302; Davison 1994. Sarawak Mus. J. 33:177–178). However, this observation took place in a setting with virtually no noise, save the calling of insects. Prior to this observation, foot flagging has been noted only once before in Rhacophoridae for another species: *Theloderma bambusicolum* (Orlov et. al. 2012. Russ. J. Herpetol. 19:23–64). This new observation may indicate that foot-flagging behavior is more widely represented in the genus *Theloderma* and perhaps the family Rachophoridae than previously known.

FIG. 1. *Theloderma truongsonense* rotating its left hind limb in a foot-flagging signal.

RANDALL D. BABB, Arizona Game and Fish Department, Region VI Office, 7200 E. University Dr., Mesa, Arizona 85207, USA; e-mail: rbabb@azgfd.gov.

TESTUDINES — TURTLES

***CHELONOIDIS CHILENSIS* (Chaco Tortoise). PREDATION.** *Chelonoidis chilensis* is the southernmost continental tortoise in the world (Cei 1986. Reptiles del Centro, Centro-oeste y Sur de la Argentina. Herpetofauna de las Zonas Áridas y Semiáridas.

Museo Regionale di Scienze Naturali, Mongr. 4. Torino, Italy). It is distributed from southwestern Bolivia and western Paraguay to northern Chubut, Argentina (Richard 1999. Tortugas de las Regiones Áridas de Argentina. L.O.L.A., Buenos Aires. 200 pp.). This species is threatened by reduced availability of suitable habitat due to agricultural expansion, leading to the destruction and fragmentation of the Espinal and Chaco forest, which are replaced by crops or ranching. Other threats include competition with sheep and goats (Prado et al. 2012. Cuad. Herpetol. 26:375–387), soil compaction by livestock (degrading tortoise nesting sites) (Waller and Micucci 1997. *In* J. Van Abbema [ed.], Proceedings: Conservation, Restoration and Management of Tortoises and Turtles–An International Conference, pp. 2–9. New York Turtle and Tortoise Society, New York); fires set to promote the regrowth of pasture (Richard 1999, *op. cit.*), and the illegal pet trade, as this species is the most traded native reptile in Argentina. This species is included on Appendix II of the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) and is considered to have a conservation status of Vulnerable by the IUCN (The IUCN Red List of Threatened Species. Version 2014.2. <www.iucnredlist.org>, accessed 07 August 2014). During the juvenile stage, this species is especially vulnerable to attack by natural predators such as ferrets, skunks, small cats, *Tupinambis* lizards, and many species of birds. Adults have fewer natural predators, which include foxes, Cougars, and Crowned Eagles (Chebez 2008. Fauna Argentina Amenazada 1:219 –231).

Here we report evidence of predation of *C. chilensis* by Wild Boars (*Sus scrofa*) in a natural environment located 45 km N of San Antonio Oeste, Río Negro Province, Argentina (40.396°S, 64.750°W, datum WGS84; elev. 125 m). Since the introduction of the Wild Boar in La Pampa province in the early twentieth century (Jaksic et al. 2002. Biol. Invasions 4:157–173), the Wild Boar population has expanded and become established in a variety of environments, and currently inhabits at least nine provinces of Argentina. In the study site, the presence of Wild Boar increased since 1972 with the construction of the Pomona Channel (pers. obs.), built to supply drinking water to San Antonio Oeste. Until that time, adult tortoise shells found were always intact. In contrast, following the establishment of Wild Boar at the site, we now find shells of adult tortoises with the plastron opened indicative of attack by Wild Boars.

We can include the Wild Boar as another potential threat to the Chaco Tortoise and urge that the presence of Wild Boar be considered during the development of strategies and priority actions to conserve this vulnerable species.

ERIKA KUBISCH, **MARIA EUGENIA ECHAVE**, and **LUIS ALBERTO ECHAVE**, Departamento de Zoología, Laboratorio de Ecofisiología e Historia de vida de Reptiles, INIBIOMA–CONICET, Centro Regional Universitario Bariloche, Universidad Nacional del Comahue, San Carlos de Bariloche (8400), Río Negro, Argentina (e-mail: erikubisch@gmail.com).

***CHELYDRA SERPENTINA* (Common Snapping Turtle). NESTING AGGREGATION.** On the evening of 15 June 2014, I witnessed four adult female *Chelydra serpentina* digging nests simultaneously. I arrived at the site (described below), at 2102 h. The skies were overcast and it had recently rained. The air temperature was 11°C and sunset was at 2129 h; I stayed until 2145 h and made several observations. Conditions were similar the previous and following evenings, except that there had been no rainfall on those occasions.

The study site, Dingman's Marsh (45.7025°N, 84.6903°W), is an impoundment formed by a 360-m earthen levy (ca. 3 m in height) built across Mill Creek by the Michigan Department of Natural Resources (MDNR) and Ducks Unlimited in 1959 to increase habitat for waterfowl. The area is managed by MDNR. It is a well-known birding site located ca. 20 km N of the University of Michigan Biological Station (Heinen and Vande Kopple 2003. Nat. Areas. J. 23:165–173), Cheboygan Co. Michigan, USA. The surface area of the marsh is ca. 3.5 km^2, and it drains an area of ca. 25 km^2.

The turtles ranged in size from ca. 26–33 cm total carapace length, estimated visually. The largest female was digging her nest in the middle of the two-track on top of the levy, and the other three were digging nests in short vegetation on the marsh side of the levy, in areas distant from nearby swamp forests such that they receive full sunlight throughout daytime. All four turtles allowed approach to within one meter without showing defensive behaviors (e.g., hissing or mouth gaping). Two of the turtles were nesting within 1 m of each other, and the third was about 10 m to the southwest of them. The fourth turtle, the largest, was another 15 m farther west along the levy two-track.

It was also apparent that all four turtles had dug in several places immediately adjacent to where I saw them. This behavior, described for other species, could be advantageous in odor-masking nests from predators (but see below), or an attempt to find appropriate incubation sites given the heterogeneity of soil particles (silts to coarse gravels) that comprise the levy.

Since I had visited at the same time the evening before, under generally similar weather conditions, and saw no nesting attempts or turtles, I suspect that this may have been a case of synchronous nesting. However, given the size of the marsh and the relative abundance of *C. serpentina*, I was surprised to see only four individuals. On another occasion several years earlier, I saw a simultaneous nesting event for *Chrysemys picta marginata* (Midland Painted Turtles) at the site, and counted over 50 individuals digging nests along the same short (ca. 100 m) stretch of levy two-track. Individual *Chelydra serpentina* are sometimes known to travel long distances overland to nest, and because the adjacent areas are mostly dense *Alnus* sp. (alder) and *Thuja occidentalis* (Northern White Cedar) swamps, other nesting turtles may have been overlooked. Other portions of the marsh are inaccessible except by boat.

Although synchronous nesting is known for a number of turtle species, there is little known about it in this species. Given the tendency of some individual *C. serpentina* to travel long distances overland to nest (Ernst and Lovich 2009. Turtles of the United States and Canada. 2nd ed. Johns Hopkins Univ. Press, Baltimore, Maryland. 827 pp.), it is difficult to conceive how this behavior could provide a predator satiation defense as hypothesized for some other species. Thus, an alternate explanation for this observation could be as simple as female turtles independently drawing on the same cue, such as day length coupled with recent rainfall (which may mask scents; Bowen and Janzen 2005. J. Herpetol. 39:649–652), to emerge and lay eggs.

I returned to the marsh the next night (16 June 2014) at 2050 h and stayed until well after sunset to see if there were any more nesting turtles. There were none observed, perhaps lending support to the previous day's event representing a synchronous nesting. The nests of the two largest turtles were destroyed and the eggs were eaten. From shell remnants, I counted 41 eggs from the largest female's nest, and 35 from the second largest female's nest. The areas were disturbed around the two smaller females' nests, but the chambers were not dug out, and there were no

eggshells nearby, suggesting that either their nests escaped predation, or they did not lay eggs. However, given the keen olfactory capabilities of the presumably mammalian predators, it seems likely that these two nests did not contain eggs. Because I lacked permission to manipulate nests I did not dig up the nests to check for intact eggs. There were no mammal tracks identifiable on the two-track, as several vehicles had driven over it the preceding day, so I could not determine the nest predator. The most common is *Procyon lotor* (Raccoon), but *Mephitis mephitis* (Striped Skunk), *Vulpes vulpes* (Red Fox), *Urocyon cinereoargenteus* (Gray Fox), several *Mustela* species (weasels), and *Didelphis virginiana* (Virginia Opossum) all occur in the area.

More observations on this species are warranted to determine whether *C. serpentina* females engage in synchronous nesting, as opposed to independently responding to similar environmental cues.

JOEL T. HEINEN, Department of Earth and Environment, Florida International University, Miami, Florida 33199, USA; e-mail: heinenj@fiu.edu.

***CHELYDRA SERPENTINA* (Snapping Turtle). RITUALIZED AGGRESSIVE BEHAVIOR.** At approx. 0715 h on 04 September 2014, two adult *Chelydra serpentina* were observed engaging in a ritualized aggressive interaction in a small pond in Champaign, Illinois, USA (40.107666°N, 88.306°W, WGS84; elev. 233 m). The observer (LM) was approx. 15–20 m from the turtles on a balcony overlooking the pond, and thus was able to film the turtles' behavior without impacting them. Sex of the turtles was not confirmed, but the behavior suggests that both individuals were males (Janzen and O'Steen 1990. Bull. Chicago Herpetol. Soc. 25:11; Hurlburt et al. 1999. Herpetol. Rev. 30:39). The two turtles were not captured or measured, but a SVL = ca. 40–50 cm and tail length = ca. 20–30 cm is a reasonable estimate for both turtles.

The two turtles began by facing each other in the middle of the narrow pond (no vegetation in the proximity) with heads submerged and carapaces visible above the water. The turtles floated in this position for a few seconds before one of the turtles lunged at the other, resulting in a collision. The turtles repeated this floating and lunging behavior for the next minute, and then both of their heads emerged from the water. At this point the turtles also cocked their tails out of the water and held them rigid while also holding their heads out of the water. The turtles then swam towards each other with heads and tails aloft, and lunged at each other's heads when they were close together. Following the violent collision, one turtle (A) began blowing bubbles under water and this was immediately reciprocated by the other turtle (B). Turtle A alternated between elevating its head out of the water to look at turtle B and submerging its head to blow bubbles for the next 30 sec, whereas turtle B kept its head out of the water for most of that time with its tail cocked out of the water (Fig. 1) and watched A. Turtle B then lowered its tail and began swimming towards turtle A and when they were close together, B lunged at A and grabbed it by the neck and the two turtles then thrust out of the water and rolled over. They separated briefly, heads emerged and they looked at each other for a few seconds, then A appeared to attempt a dive and B swam to where A was and stopped the dive. B partially mounted the shell of A, and the two faced off again with only the carapaces out of the water. They floated in this manner for approx. 15 seconds and then came together resulting in a collision and immediate parting. They continued to engage in this behavior for another 2–3 min. At this point A elevated its head and tail, and B lunged at A and appeared to grab

FIG. 1. Still image of an adult Snapping Turtle engaging in ritualized posturing with tail and head out of the water, while the other adult Snapping Turtle blows bubbles.

A's neck. When they separated they both elevated their heads and tails, and A appeared to blow a few bubbles. They looked at each other for a few sec and then B began swimming towards A with its head out of the water, and A turned and tried swimming away. B caught up to A and partially mounted A's shell and appeared to lunge for A's tail, causing A to spin around and attempt to protect its extremities. B relented, allowing A to swim off towards the edge of the pond.

Aggressive interactions between Snapping Turtles have been documented (e.g., Raney and Josephson 1954. Copeia 1954:228; Hammer 1969. J. Wildl. Manag. 33:995–1005; Janzen and O'Steen 1990, *op. cit.*), this is the first recorded instance of ritualized agonistic behavior that included both combatants elevating head and tails out of the water during the confrontation. This behavior may allow the rivals to gauge each other's size and perhaps facilitate a non-violent resolution if one is clearly larger. Bubble-blowing is also an example of ritualized behavior and was noted in one other instance (Raney and Josephson 1954, *op. cit.*). It is unclear what role bubble-blowing serves, although it presumably may also be a signal of size. A short video of the described interaction is available at: http://wwx.inhs.illinois.edu/research/videos/snapping-turtle/.

LOREN MERRILL, University of Illinois, Urbana-Champaign, Illinois Natural History Survey, 1816 S. Oak St. Champaign, Illinois 61820, USA; e-mail: loren21@illinois.edu.

***CHELYDRA SERPENTINA* (Common Snapping Turtle). UNUSUAL NESTING BEHAVIOR.** Nesting behavior in Snapping Turtles has been widely studied at many locations (Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed. John Hopkins Univ. Press, Baltimore, Maryland. 827 pp.), including our study site at Gimlet Lake, Garden Co., Nebraska, USA, on the Crescent Lake National Wildlife Refuge (Iverson et al. 1997. Herpetologica 53:96–117). At this site (as well as at other northern sites; references above), Snapping Turtles are known to oviposit a maximum of only one clutch of eggs per year. We are unaware of a previous published account of a female Snapping Turtle digging and covering a complete nest twice in less than one week.

On 2 June 2012 an individual female *C. serpentina* emerged from the water and engaged in normal nesting behavior. Upon completion of nesting, her body and clutch measurements were taken (maximum carapace length: 35.7 cm, post-nest body mass: 9300 g, clutch size: 56, mean egg mass: 13.44 g) and she was released back to the lake from which she emerged. Five days later (7 June 2012), the same individual emerged and proceeded to dig

and cover a complete nest. Measurements were once again taken as she left the completed nest (post-nest body mass: 9800 g) and she was again released to return to the water. Upon immediate nest excavation, no eggs were present. Because the nest was fully constructed and covered, this observation cannot be considered a "false crawl" (e.g., Rumbold et al. 2001. Restoration Ecol. 9:304–310) or a "false nest" (e.g., Nelson et al. 2009. Chelon. Conserv. Biol. 8:66–73). We have not previously observed this behavior in 34 years of work at this site (>> 650 nests examined).

We have observed Painted Turtles (*Chrysemys picta*) at this site excavate and cover empty nests some days after hormonal induction of oviposition with oxytocin (Iverson and Smith 1993. Copeia 1993:1–21). However, the female Snapping Turtle had never been captured before, so the physiological mechanism that drove her to construct a second, empty nest is unknown.

The staff of the Crescent Lake National Wildlife Refuge permitted and supported our long-term research at this site.

***DOGANIA SUBPLANA* (Malayan Softshell Turtle). DIET AND ISLAND POPULATION.** *Dogania subplana* is a relatively small (carapace length [CL] to 350 mm) trionychid occurring from southern Myanmar and Thailand south through Peninsular Malaysia and Sumatra to Java, and east to Borneo and possibly the Philippines (Smith 1931. The Fauna of British India, including Ceylon and Burma. Vol. 1. Loricata and Testudines. Taylor and Francis, London. 185 pp.; Iverson 1992. A Revised Checklist with Distribution Maps of Turtles of the World. Privately printed, Richmond, Indiana. 363 pp.). Despite being widespread and even common in many areas (Nutaphand 1979. The Turtles of Thailand. Siam Farm, Bangkok. 222 pp.), the ecology of *D. subplana* remains poorly known. In particular there is a notable paucity of information on diet. Although general accounts suggest *D. subplana* is omnivorous and consumes fish, crustaceans, insects, clams, aquatic snails, fruits, and algae (Bonin et al. 2006. Turtles of the World. Johns Hopkins University Press, Baltimore, Maryland. 416 pp.; Cox et al. 2010. A Photographic Guide to Snakes and Other Reptiles of Thailand and South-east Asia. Asia Book Co., Ltd., Bangkok. 144 pp.), empirical reports based on the analysis of stomach contents or feces appear lacking in the scientific literature.

On 19 December 2013, we found the fresh carcass of a male *D. subplana* (CL = 178 mm; plastron length = 140 mm) on Lampi Island in Lampi Island National Park, Boke Pyin Township, Tanintharyi Region (formerly "Division"), Myanmar. Lampi Island National Park (205 km^2) is located approximately 25 km from the mainland and encompasses parts of the Myeik Archipelago. Lampi Island is characterized by steep terrain (to 455 m) covered in relatively undisturbed tropical evergreen forest (Beffasti and Galanti 2011. Myanmar Protected Areas: Context, Current Status and Challenges. Ancora Libri, Milan, Italy. 153 pp.). The turtle carcass was found in Yeaw Chaung (= creek), a spring-fed, rocky stream with a sand-gravel substrate that drains hills on the eastern side of the island. The carcass was found at an elevation of < 5 m above sea level, approximately 175 m upstream from where the stream empties into the Andaman Sea (10.86660°N, 98.23966°E; India-Bangladesh datum). Yeaw Chaung is similar to hill stream habitat described for *D. subplana* in Malaysia and Thailand (Smith, *op. cit.*; Cox et al., *op. cit.*). We were unable to determine how the turtle died as the carcass exhibited no apparent injuries or signs of predation. We removed the stomach and intestinal tract during a cursory necropsy; the former was filled with the fresh remains of a small crab (pincer length = 15 mm) of an undetermined species. Crabs were abundant among the rocks in the streambed as well as in mangroves at the creek mouth. To our knowledge, this is the first empirically derived report concerning the diet of *D. subplana*.

Our finding is also the first record of *D. subplana* from Lampi Island and represents one of the few specimen-based records from Myanmar. The only previous records of *D. subplana* in Myanmar are from Myeik (formerly "Mergui") and nearby coastal islands (Smith, *op. cit.*; Iverson, *op. cit.*). The occurrence of *D. subplana* on offshore islands in Myanmar is not unexpected. In Malaysia, *D. subplana* occurs on "many smaller islands where other trionychids are never found" (Smith, *op. cit.*). *Dogania subplana* has also been reported on Singapore and offshore islands in Thailand and Indonesia (Iverson, *op. cit.*; Lim and Lim 1992. A Guide to the Amphibians and Reptiles of Singapore. Singapore Science Centre, Singapore. 160 pp.). van Dijk (1998. The Natural History of the Elongated Tortoise *Indotestudo elongata* [Blyth, 1853] [Reptilia: Testudines] in a Hill Forest Mosaic in Thailand, with Notes on Sympatric Turtle Species. Ph.D. dissertation, National University of Ireland at Galway. 255 pp.) speculated that *D. subplana* populations on continental shelf islands are Pleistocene relicts that became isolated on mountains and hilltops by rising sea levels; however, more recent dispersal from mainland freshwater habitats cannot be ruled out.

We thank the Ministry of Environmental Conservation and Forestry for granting permission to conduct fieldwork in Myanmar, and are grateful for the field assistance provided by Thein Naing Aung and Forest Department Rangers. Research in Myanmar was made possible by generous grants from Turtle Conservation Fund and Andy Sabin and the Sabin Family Foundation. We thank Peter Paul van Dijk and Lewis Medlock for providing literature and thoughtful commentary on this manuscript. The findings and conclusions in this article are those of the authors and do not necessarily represent the views of the U.S. Fish and Wildlife Service.

***GLYPTEMYS INSCULPTA* (Wood Turtle). NESTING HABITAT AND BEHAVIOR.** *Glyptemys insculpta*, a species native to the northeastern United States and southeastern Canada, is imperiled due to a variety of factors including habitat degradation and loss (Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed. Johns Hopkins Univ. Press, Baltimore, Maryland. 827 pp.). Nesting habitat, typified by well-drained, bare sand, gravel, or soil with ample sun exposure, has been implicated as a limiting factor for *G. insculpta* populations (Buech et al. 1997. *In* Proceedings: Conservation, Restoration, and Management of Tortoises and Turtles—An International Conference, pp. 389–391. New York Turtle and Tortoise Society, New York; Ernst and Lovich 2009, *op. cit.*). On 10 June 2014 at 1815 h, we observed a

female *G. insculpta* exhibiting preliminary nesting behavior on a sand patch located approximately 3 m from the edge of a stream within a logged section of Caledonia State Park, Pennsylvania (39.9116°N, 77.4726°W, datum WGS84; elev. 290 m). The sand patch in which the *G. insculpta* was observed and several nearby sand patches appeared to have been created by flood-borne sand deposition around logging-generated deadwood (e.g., logs, stumps). The turtle's tracks in the sand encompassed two depressions that appeared to be incomplete nest cavities excavated by the observed female. These depressions may be consistent with the "false start" sequence of preliminary nesting behavior observed in *G. insculpta* in Michigan by Harding and Bloomer (1979. HERP, Bull. New York Herpetol. Soc. 15[1]:9–26). Additionally, we observed that several portions of the *G. insculpta* carapace were covered in sand. Female *G. insculpta* often coat their carapace with wet sand as a prelude to nesting (Harding and Bloomer 1979, *op. cit.*). Additional turtle tracks were noted approximately 10 m downstream in another sand patch.

Anthropogenic effects on streams and riparian habitats (e.g., damming, channelization, land use alterations) often negatively impact *G. insculpta* nesting habitat (Buech et al. 1997, *op. cit.*). However, in this case, logging debris may have enhanced nesting habitat by leading to the creation of sand patches and increasing sun exposure. This observation may be pertinent to *G. insculpta* habitat conservation as the addition or maintenance of deadwood within stream flood plains may create or enhance suitable *G. insculpta* nesting habitat. However, further research is needed to determine whether nests located within these and similar sand patches are successful.

We thank Cotter Nunan and Robyn E. Woodley for providing transportation to Caledonia State Park. These observations were made during a random encounter while hiking. All observations were conducted visually, and the turtle and habitat were not disturbed during the course of these observations.

***GOPHERUS AGASSIZII* (Mohave Desert Tortoise) and *CROTALUS MITCHELLII* (Speckled Rattlesnake). BURROW ASSOCIATE.** The burrows of Desert Tortoises (*Gopherus agassizii*) present a unique microhabitat that provides shelter from extreme heat, cold, and aridity, as well as offering protection from predators (Bulova 2002. J. Therm. Biol. 27:175–189). Temperatures inside the burrow are known to be more stable than the ambient environment which can become lethal to most desert species (Walde et al. 2009. Southwest Nat. 54:375–381). A review of commensals reported 31 species (23 vertebrates, 8 invertebrates) using Desert Tortoise burrows (Luckenbach 1982. *In* Bury [ed.], North American Tortoises: Conservation and Ecology. pp. 1–38. Wildl. Res. Report 12, U.S. Fish and Wildlife Service, Washington, D.C.) and few species have been added since (Walde and Lindey 2009. Herpetol. Rev. 40:75; Walde et al. 2009, *op. cit.*; Germano and Perry 2012. Herpetol. Rev. 43:127). However, over 360 commensals for the Gopher Tortoise (*Gopherus polyphemus*) have been reported (Jackson and Milstrey 1989. *In* Diemer et al. [eds.], Gopher Tortoise Relocation Symposium Proceedings. pp. 86–98. State of Florida Game and Fresh Water Fish Commission Nongame Wildlife Program Technical Report No. 5) and as such it is considered to be a keystone species (Eisenberg 1983. *In* Bryant and Franz [eds.], The Gopher Tortoise: a Keystone Species, pp. 1–4. Proceedings of the 4th Annual Meeting of the Gopher Tortoise Council). The large disparity in the number of commensals between these two *Gopherus* species is presumably due to the difference in overall faunal diversity between their ranges. However, although the number of commensal species reported for Mohave Desert Tortoises is comparatively low, it is possible that they are understudied and underreported, and thus their role in desert ecology is not fully known.

During Mohave Desert Tortoise surveys approximately 45 km NE of Barstow, California, USA, on 7 July 2009 at 0838 h, an adult male Mohave Desert Tortoise was observed sharing a burrow with a Speckled Rattlesnake (*Crotalus mitchellii*). The burrow mouth faced due north and was in a caliche formation along the edge of a wash at the base of the Alvord Mountains in the western Mojave Desert. Evidence of an old Desert Woodrat (*Neotoma lepida*) midden was present in the burrow and burrow mouth. Average air temperature for that time of day is approximately 32°C, with ground temperatures of ≈40°C, while burrow temperatures remain stable at around 31°C (Walde et al. 2009, *op. cit.*).

Seven species of snakes are documented to use Mohave Desert Tortoise burrows, including four species of rattlesnakes (Luckenbach 1982, *op. cit.*; Lovich 2011. Herpetol. Rev. 42:421). This is the first documentation of a Speckled Rattlesnake using a Desert Tortoise burrow. Summer foraging activity for Speckled Rattlesnakes is known to be primarily nocturnal due to high temperatures during the day (Ernst and Ernst 2003. Snakes of the US and Canada. Smithsonian Institute, Washington, DC. 668 pp.). It is possible that the Speckled Rattlesnake was foraging in the burrow, perhaps the night before, as several prey species of the Speckled Rattlesnake have been shown to utilize Mohave Desert Tortoise burrows (Luckenbach 1982, *op. cit.*). It could also have been using the burrow as a thermal refuge.

Funding for the project during which this observation was made was provided by DPW Environmental at the National Training Center, Fort Irwin, California.

ANGELA M. WALDE (e-mail: angiecone@hotmail.com), **ANDREW D. WALDE** (e-mail: awalde@hotmail.com), Walde Research & Environmental Consulting, 8000 San Gregorio Rd., Atascadero, California 93422; USA; **CHARLIE JONES**, Noble Creek Biological Consulting, 4207 SE Woodstock Blvd., #360, Portland, Oregon 97206, USA (e-mail: charlie@noblecreekbiological.com).

***MACROCHELYS TEMMINCKII* (Alligator Snapping Turtle). JUVENILE BASKING.** *Macrochelys temminckii* is a large, secretive freshwater turtle found in rivers and associated waters of several southeastern states (Pritchard 1989. The Alligator Snapping Turtle: Biology and Conservation. Milwaukee Public Museum, Milwaukee, Wisconsin. 104 pp.; Lovich 1993. SSAR Cat. Amer. Amphib. Rept. 562.1–562.4; Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 578 pp.). Little is known about the behavior of this cryptic species, and it is rarely observed basking. A recent report documented an adult *M. temminckii* basking (Selman et al. 2009. Herpetol. Rev. 40:79) in Mississippi, and rare instances of observed aerial basking for juveniles have been reported in other locations including Texas and Florida (Ewert 1976. Herpetologica 32:150–156; Farr et al. 2005. Herpetol. Rev. 36:168; Thomas 2009. Herpetol. Rev. 40:336). A hatchling caught in a basking trap in Mississippi was presumably basking, although the behavior was not directly witnessed (Shelby and Jenson 2002. Herpetol. Rev. 33:304). A recent review documented basking by *M. temminckii* in north Louisiana (Carr et al. 2011. IRCF Reptiles & Amphibians. 18:2–5); of note all nine prior instances involved

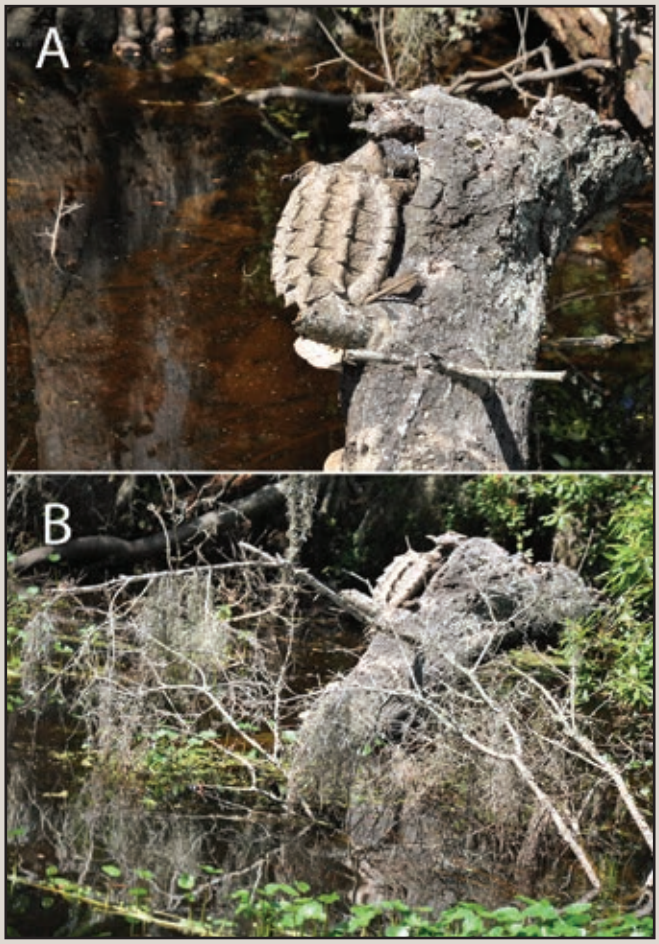

FIG. 1. Alligator Snapping Turtle *(Macrochelys temminckii)* basking in coastal Louisiana.

single individuals basking. Herein we report on two juvenile *M. temminckii* observed basking on the same afternoon in coastal Louisiana.

On 3 May 2014, RB observed two basking juvenile *M. temminckii* (estimated mass less than 4.5 kg) approximately 0.8 km apart in a swamp just south of Centerville, St. Mary Parish, Louisiana, USA. The water depth was approximately 75 cm and clear. It was sunny and the water temperature was 22.2°C. The air temperature was estimated at approximately 28°C by RB; the measured maximum temperature in Grand Chenier, Louisiana (similar latitude) that day was 24.4°C. The first specimen was observed at approximately 1450 h by RB and a companion travelling slowly in an 18-foot flat-bottom boat with a 200-hp motor. The turtle was observed basking on a submerged tree limb that completely crossed the canal; the log was initially overlooked by the boat operator. When the boat motor inadvertently nudged the log upon which the turtle was basking it did not disturb the turtle, but after passing the turtle the observers reversed the boat to attempt to observe it again at a closer distance. At this point the turtle entered the water; it was thus observed for approximately 90 seconds.

The second specimen was seen at approximately 1520 h basking on a log (Fig. 1A) approximately 60 cm above the water (Fig. 1B), despite other limbs at a lower elevation being readily available for resting platforms in the immediate vicinity. The specimen remained motionless and appeared lifeless, and was approached to within approximately 3–4 m, with the boat motor running. It was observed for several minutes, and a series of photographs were taken. The water body was a "dead end" canal and thus the second turtle was observed again as the observers retraced their route to exit the wetlands; each observation period was estimated to last some five minutes. The first of thirteen photographs was taken at 1524 h as RB entered the dead-end canal, and the last photo on the return trip was taken at 1612 h; thus the turtle was presumably basking at least 48 minutes. When seen initially, the turtle's carapace was very dry suggesting it had been basking for some time prior to being observed, and on the return trip the turtle was still completely dry, and the body position was unchanged. Until recently, most prior observations of basking in this species were limited to brief observations lasting only a matter of minutes (maximum about 12 minutes in Farr et al., *op. cit.*); Carr et. al. (*op. cit.*) documented basking for 58 minutes in their third observation reported. In some cases in the accounts previously cited, basking time for the turtle described was interrupted when the turtle was captured and handled by investigators or approached closer for attempted photography, causing it to retreat into the water.

The height above the waterline at which the second turtle was basking is clearly shown in Fig. 1B; both Farr et al. (2005, *op. cit.*) and Selman and Willig (2010. Herpetol. Rev. 41:486) documented similar elevated locations for basking and climbing ability in *M. temminckii* but we are not aware of photographs to document this behavior. Carr et al. (2011, *op. cit.*) provided photo-documentation of this species basking on railroad ties in Ouachita Parish in north Louisiana.

We are not aware of any prior instances of two *M. temminckii* being observed basking on the same day; indeed all nine prior documented cases of basking were of single individuals (Carr et al. 2011, *op. cit.*). To our knowledge this is also the first documentation of basking, including photos, for *M. temminckii* in coastal Louisiana. Researchers have suggested observations of this very rare behavior should be documented (Selman et al. 2009, *op. cit.*) and a number of explanations for basking behavior in this cryptic species were recently reviewed (Carr et al. 2011, *op. cit.*).

We acknowledge Will Selman for providing helpful references and Elizabeth Bordelon for assistance with details on the observations.

RUTH M. ELSEY, Louisiana Department of Wildlife and Fisheries, Rockefeller Wildlife Refuge, 5476 Grand Chenier Highway, Grand Chenier, Louisiana 70643, USA (e-mail: relsey@wlf.la.gov); **RUSSELL BOURGEOIS**, 215 Roland Lane, Jeanerette, Louisiana 70544, USA.

***MALACLEMYS TERRAPIN CENTRATA* (Carolina Diamond-backed Terrapin). TWINNING.** On 3 July 2014 a clutch of 9 eggs collected from a female Diamond-backed Terrapin (carapace length = 195.0 mm, plastron length = 174.0 mm, carapace width = 149.0 mm, depth = 81.0 mm, mass = 1234.0 g) originating from Charleston Harbor, South Carolina, USA (32.748272°N, 79.896714°W), began hatching after incubating for 49 days at a constant temperature of 31°C. Initially, only four eggs hatched successfully, producing four hatchlings that averaged 31.1 mm carapace length, 27.4 mm plastron length, 26.7 mm carapace width, 15.9 mm depth and a mass of 8.7 g. On 4 July 2014 the fifth and final egg of the clutch hatched, revealing two hatchlings joined together by the external yolk (Fig. 1). While both individuals were undersized, one was significantly larger than the other (larger hatchling: carapace length = 25.5 mm, plastron length =

FIG. 1. Twin hatchling Diamondback Terrapins joined by the external yolk.

FIG. 2. Twin hatchling Diamondback Terrapins separated and feeding in water.

FIG. 1. *Melanochelys tricarinata*, male from the campus of the Wildlife Institute of India.

FIG. 2. Portion of tail of *Amphiesma stolatum* defecated by *Melanochelys tricarinata*.

21.3 mm, carapace width = 20.5 mm, depth = 12.7 mm, mass = 4.33 g; smaller hatchling: carapace length = 18.0 mm, plastron length = 14.5 mm, carapace width = 15.7 mm, depth = 10.4 mm, mass = 1.91 g). Both hatchlings were washed with de-ionized water, placed in a plastic container with moist paper towels, and returned to the incubator. Each day, the moist paper towels were replaced, containers were cleaned, and the hatchlings were placed back into the incubator. After 3 days the hatchlings separated from one another naturally. By 9 August 2014 both hatchlings' plastrons were completely healed and they were placed in water and offered food (Fig. 2). By 25 August 2014, both hatchlings had eaten small amounts of fish and periwinkle snails, were alert, and seemed to be in good health.

Identical twin Diamond-backed Terrapins, attached by the external yolk, have been reported once previously (Hildebrand 1938. J. Hered. 29[7]:243–254); however, this was the only example he observed in over 25 years and an estimated 100,000 artificially-hatched Diamond-backed Terrapin eggs in Beaufort, North Carolina. The twins were said to be well formed, although slightly undersized, measuring about 18 mm in length. Shortly after discovery, both individuals were reported to have died.

ANDREW M. GROSSE (e-mail: grossea@dnr.sc.gov), and **ERIN M. LEVESQUE** (e-mail: levesquee@dnr.sc.gov), South Carolina Department of Natural Resources, Marine Resources Research Institute, 217 Fort Johnson Road, Charleston, South Carolina 29412, USA.

***MELANOCHELYS TRICARINATA* (Tricarinate Hill Turtle). DIET.** *Melanochelys tricarinata* is distributed across northern and eastern India, Nepal, Bhutan, and Bangladesh, and inhabits moist deciduous Sal (*Shorea robusta*) forests, evergreen forests, and riverine grassland (Das 2009. Chelonian Res. Monogr. [5]:025.1–025.5; Wangyal et al. 2012. Chelonian Conserv. Biol. 11:268–272). It is omnivorous, feeding on earthworms, insects, and a variety of plant materials (Kumar et al. 2010. Herpetol. J. 20:139–146). As part of an ongoing mark-recapture study, on 10 July 2014, we captured a male *M. tricarinata* (Fig. 1) at 1630 h in a natural *Shorea robusta* forest within the Wildlife Institute of India Campus (77.97411°E, 30.28330°N), Dehradun, Uttarakhand State, northern India. The turtle measured 156.63 mm SCL, 98.50 mm SCW, 131.88 mm PL, and weighed 464 g. Shortly after capture, it defecated seeds of *Ficus* sp. and part of a tail belonging to a snake, *Amphiesma stolatum* (Fig. 2). The identity of the latter item was based on characteristic buff striped mark on tail, and tail stripe length of 64.40 mm and maximum width of 7.12 mm. North American turtle species, such as *Apalone ferox*, *Terrapene carolina*, *Trachemys scripta*, *Chelydra serpentina*, and *Macroclemys temminckii* (Dodd 2001. North American Box Turtles: A Natural History. University of Oklahoma Press, Norman, Oklahoma. xvi + 231 pp.; Ernst and Lovich 2009. Turtles of the United States and Canada. 2nd ed. Johns Hopkins University Press, Baltimore, Maryland. 827 pp.) and the Australian *Chelodina rugosa* (Cann 1998. Australian Freshwater Turtles. Craft Print Pte Ltd and Beaumont Publishing Pvt. Ltd, Singapore. 292 pp.) are known to feed on snakes through predation and/or scavenging. This is the first record of a snake in the diet of an Indian turtle species.

We thank the Uttakhand Forest Department for study permission and Indraneil Das for his suggestions on this manuscript.

ABHIJIT DAS (e-mail: abhijit@wii.gov.in), and **R. SURESH KUMAR** (e-mail: suresh@wii.gov.in), Endangered Species Management Depart-

ment, Wildlife Institute of India, Chandrabani, Dehradun, Uttarakhand, India

***MESOCLEMMYS TUBERCULATA* (Tuberculate Toad-headed Turtle). HATCHLINGS.** The chelid turtle *Mesoclemmys tuberculata* occurs in eastern Brazil, in the Rio São Francisco and adjacent drainages, recorded mainly in the Caatinga and at some localities in the Atlantic Forest and Cerrado; it is a medium-sized species that may reach a carapace length of 25–30 cm (Ernst and Barbour 1989. Turtles of the World. Smithsonian Inst. Press, Washington, DC. 313 pp.). This species is used as food and medicinal purposes by humans in this semi-arid region of Brazil (Alves et al. 2012. J. Ethnobiol. Ethnomed. 8:1–29).

On 8 November 2013, during a faunal rescue operation in conjunction with the Project of Integration of São Francisco river (PISF) within the basins of septentrional northeastern, we collected eight eggs belonging to an unidentified species of turtle. The eggs were found at the site of the future dam of the Jati Reservoir (7.703314°S, 39.008587°W), municipality of Jati, state of Ceará, Brazil. The local environment was a small dry area, where a tractor was clearing dense regrown vegetation. After we collected the eggs, the tractor cleared what was left of the area. Of the total of eight eggs collected, two remained intact and were placed in a folded tissue and sealed in a plastic bag for transport to the Laboratório de Morfofisiologia of the Núcleo de Ecologia Molecular (NECMOL) in the Centro de Conservação e Manejo de Fauna da Caatinga (CEMAFAUNA-CAATINGA). The eggs were then placed in a plastic container (2000 ml) on a substrate of vermiculite, and incubated at 27–30°C. Five months later, on 10 April 2014, two hatchlings emerged (Fig. 1). They were identified as *M. tuberculata* (Ernst and Barbour, *op. cit.*), and measurements were taken using a digital caliper (precision = 0.01 mm) and a precision balance (1 g).

The morphometric data for two hatchlings were: carapace length (CL1: 39.0 mm, CL2: 37.1 mm), carapace width (CW1: 25.8 mm, CW2: 25.5 mm), shell height (SH1: 14.0 mm, SH2: 13.4 mm), plastron length (PL1: 31.7 mm, PL2: 29.4 mm), plastron width (PW1: 21.2 mm, PW2: 20.0 mm), and body mass (BM1: 10.0 g, BM2: 8.8 g). Previously reported clutch size for *M. tuberculata* was 4–9 eggs (32 × 26 mm, 11.4–13.3 g), with a hatchling carapace length of 37 mm (Grossmann and Reimann 1991. Sauria 13:3–6), in general agreement with the present report.

The specimens of *M. tuberculata* (MFCH 3564–3565) were deposited in the Herpetological Collection of the Centro de Conservação e Manejo de Fauna da Caatinga (CEMAFAUNA-Caatinga/UNIVASF), Petrolina, Pernambuco, Brazil. We thank the Ministério da Integração Nacional for financial support. IBAMA provided the collecting permit (#95/2012 Process n° 02001.003718/94-54).

FIG. 1. Lateral view of the carapace (left) and plastron view (right) of a hatchling *Mesoclemmys tuberculata* (carapace length 39.0 mm, plastron length 31.7 mm). Note the two chin barbels and the remains of the yolk sac on the plastron.

***PODOCNEMIS UNIFILIS* (Yellow Spotted Amazon River Turtle). PREDATION.** *Podocnemis unifilis*, like other large river turtles, is characterized by having delayed maturity and low natural adult mortality, with a much higher mortality of eggs and hatchlings, which are reported to be preyed upon by vultures (*Coragyps atratus* and *Cathartes aura*), Carcará (*Polyborus plancus*), Jaburu (*Jabiru mycteria*), tegus (*Tupinambis teguixin*), Coati (*Nasua nasua*), and a mustelid (*Cerdocyon thous*) (Salera Junior et al. 2009. Acta Amazonica 39:207–214). These authors also reported Black Caiman (*Melanosuchus niger*), Jaguar (*Panthera onca*), and Cougar (*Puma concolor*) preying on females during the nesting season on the Javaes River, Tocantins, Brazil. The Jaguar and Cougar consumed the turtles at the nesting beach but it was impossible to determine from their paper if the caiman predation took place on land or in the water. Soares (2000. MS thesis. INPA, Manaus) on the Rio Guapore, Rondônia, Brazil, Emmons (1989. J. Herpetol. 23:311–314) on the Arataye River, French Guiana, and Hildebrand et al. (1997. La Tortuga Charapa [*Podocnemis expansa*] en el Río Caquetá, Amazonas, Colombia: Aspectos de su Biología Reproductiva y Técnicas para su Manejo. Disloque Editores, Ltda., Santafé de Bogotá. 152 pp.) on the Caqueta River, Amazonas, Colombia, all reported *Panthera onca* and *Pa. concolor* consuming nesting *P. unifilis* and *P. expansa*.

The 385,000-ha Rio Trombetas Biological Reserve (1.25°S, 56.83333°W; WGS84) is located in the Municipality of Oriximiná, Pará State, Brazil. During the dry season, sand beaches are exposed as the water level of the river recedes, providing nesting areas for *Podocnemis expansa, P. unifilis*, and *P. sextuberculata*. This is the first documentation of a female *Podocnemis unifilis* apparently leaving the water in an attempt to escape predation by a Black Caiman (*Melanosuchus niger*) in the Trombetas Reserve. At 0840 h on 11 October 2013, during nesting surveys we observed the deep tracks and body drag of a Black Caiman where it had lunged out of the water making a 6-cm deep impression in the wet sand, and 4-cm deep tracks, suggesting a running gait. A turtle was captured within 2 m of the shore line, as evidenced by turmoil in the sand, fresh blood, and egg shells and yolk splattered in a 1.5-m diameter area; only one fragment of the 9th–10th right marginal scute of the turtle remained on the beach. From this carapace fragment, the egg shells, and the tracks, the turtle was identified as *P. unifilis* (Fig 1. A–C). Based on the tracks of the turtle, we believe it was not nesting, nor did it appear to be walking at a leisurely pace looking for a nest site, but rather was running in an attempt to escape predation.

Financial and logistical support for the study were provided by Projeto Tartarugas da Amazônia and REBIO Trombetas (ICMBio), CNPq provided a scholorship for F. A. G. Cunha. This research was authorized by permit N°40084-3/2013 ICMBio.

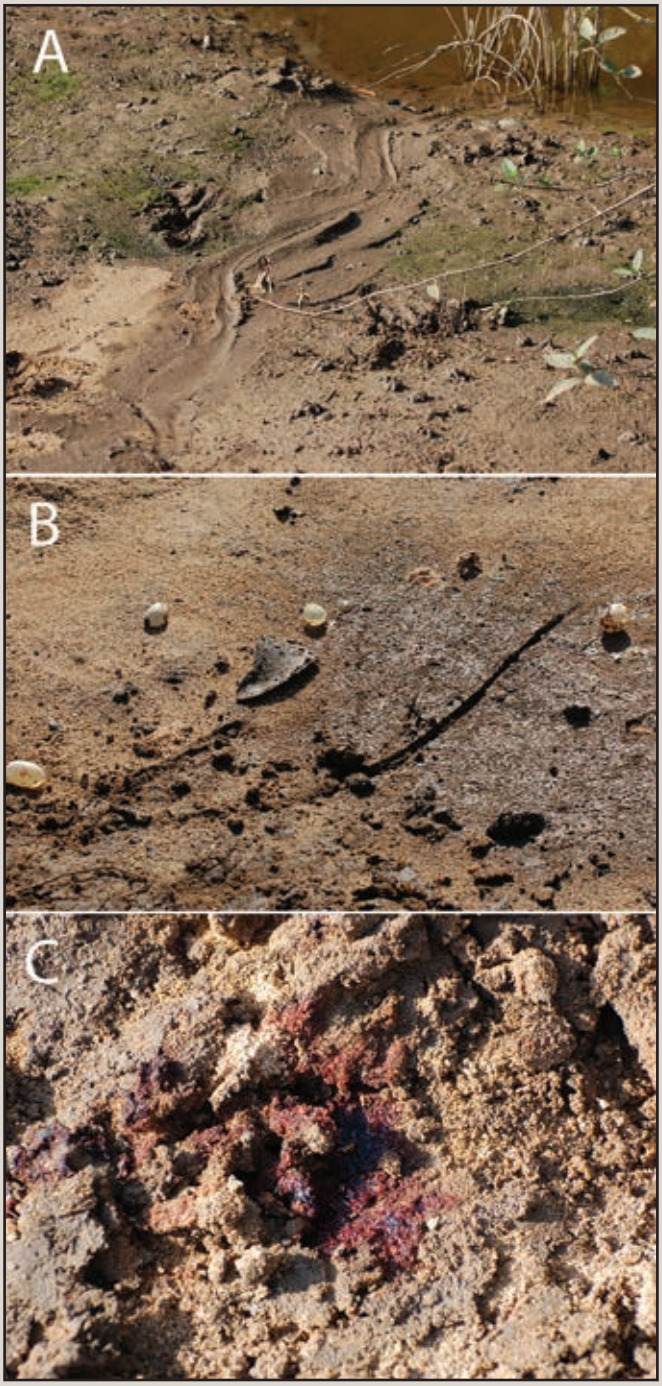

FIG. 1. A) Tracks of *Melanosuchus niger* leaving the water; by the depth of the tracks and body drag it appears as though it was lunging in rapid pursuit of a female *Podocnemis unifilis*, which shows, by its widely spaced tracks, that it left the water in an attempt to escape predation. Note that the caiman's tracks returning to the water were less distinct and the body drag was shallower, suggesting it was moving at a slower pace. B) Broken egg shells and a part of the carapace of the turtle. C) Blood and disturbed soil.

FABIO A. G. CUNHA (e-mail: fabioagcunha@gmail.com), **RICHARD C. VOGT**, BADPI and CBIO, Instituto Nacional de Pesquisas da Amazônia (INPA), Av. André Araújo, 2936, Petrópolis, CEP 69.067-375 Manaus, Amazonas, Brazil (e-mail: vogt@inpa.gov.br).

***PSEUDEMYS ALABAMENSIS* (Alabama Red-bellied Cooter). MAXIMUM SIZE.** The maximum straight-line carapace length (SCL_{max}) for *Pseudemys alabamensis* is currently given as 33.5 cm for a female and 29.5 cm for a male (Ernst and Lovich 2009. Turtles of the United States and Canada. Johns Hopkins University Press, Baltimore, Maryland. 827 pp.; Mount 1975. The Reptiles and Amphibians of Alabama. University of Alabama Press, Tuscaloosa, Alabama. 347 pp.) From 1995 to 2000, we captured, marked, and measured over 500 specimens in Baldwin and Mobile counties, Alabama, USA. In 1999, we captured a female *P. alabamensis* in a hoop trap array near Gravine Island on the Tensaw River in Baldwin Co., Alabama that had a SCL_{max} of 38.3 cm and weighed 7.42 kg. From 1998 to 2001, we trapped 25 females from locations in the Blakeley River and Tensaw River (near Gravine Island), Baldwin Co., Alabama, that exceeded 33.5 cm SCL_{max} (33.8–38.3 cm). During this sampling, we also captured two very large males (29.9 cm SCL_{max}, 3.42 kg and 29.7 cm SCL_{max}, 2.66 kg) that exceeded the 29.5 cm maximum SCL_{max} given for males of *P. alabamensis* in the literature. All of these turtles were marked by drilling their marginal scutes, and their marking patterns may be obtained by contacting the authors.

DAVID H. NELSON, Department of Biology, University of South Alabama, Mobile, Alabama 36688, USA (e-mail: dnelson@southalabama.edu); **WILLIAM M. TURNER,** Sea to See Program Director, Florida State University, Tallahassee, Florida 32306, USA (e-mail: bturner@bio.fsu.edu).

***TERRAPENE ORNATA LUTEOLA* (Desert Box Turtle). DIET.** Much of the published information regarding the feeding ecology of *T. ornata* draws from studies on the subspecies *T. o. ornata* (Legler 1960. Univ. Kansas Publ. Mus. Nat. Hist. 11:527–669; Ernst and Lovich 2009. Turtles of the United States and Canada. 2nd ed. Johns Hopkins University Press, Baltimore, Maryland. 827 pp.). Less information is available describing the feeding habits of the westernmost subspecies, *T. o. luteola*. The available literature describes *T. o. luteola* as feeding on beetles, grasshoppers, millipedes, and unidentified plant material (Platt et al. 2012. Herpetol. Rev. 43:640), scavenging on a dead Round-tailed Horned Lizard, *Phrynosoma modestum* (Germano 2009. Herpetol. Rev. 40:80), and feeding on Thread-leaf Groundsel petals (*Senecio flaccidus*; Murray 2013. Herpetol. Rev. 44:134–135). Here we report on additional observations of diet in *T. o. luteola* from several populations in New Mexico, USA. On 20 July 2010 we encountered an adult female *T. o. luteola* feeding on the remains of a road-killed Lesser Earless Lizard, *Holbrookia maculate*, on a dirt road in

PHOTO BY IAN W. MURRAY

FIG. 1. Adult male *Terrapene ornata luteola* feeding on Hot Springs Globemallow, *Sphaeralcea polychroma*.

central New Mexico (34.46878°N, 106.57305°E, datum WGS84; 1615 m elev.). Additionally, while field processing (for an unrelated study) another central New Mexico (34.59945°N, 106.66008°E, WGS84; 1545 m elev.) adult female *T. o. luteola* on 24 September 2007 she defecated the scaled remains of a Greater Short-horned Lizard, *Phrynosoma hernandesi*, which had presumably also been scavenged as carrion. On 2 September 2009 at 1925 h on the Sevilleta National Wildlife Refuge ca. 67 km S of Albuquerque, New Mexico (34.37210°N, 106.68092°E, datum WGS84; 1588 m elev.) we observed an adult male *T. o. luteola* feeding on the flower buds of a Hot Springs Globemallow, *Sphaeralcea polychroma* (Fig. 1). On 10 August 2002 between 0926–0945 h ca. 20 km S of Alamogordo, New Mexico (32.69755°N, 105.97853°E, datum WGS84; 1225 m elev.) we noted an adult female *T. o. luteola* feeding on the pads of a small Purple Prickly Pear Cactus, *Opuntia macrocentra*, as well as an adult male (ca. 60 m away) eating the dried remains of a Long-nosed Snake, *Rhinocheilus lecontei*. We additionally witnessed an adult male *T. o. luteola* eating a road-killed Texas Horned Lizard, *Phrynosoma cornutum*, on a nearby road (32.71292°N, 105.98387°W, datum WGS84; 1224 m elev.) on the morning of 15 July 2002. These observations emphasize the opportunistic nature of foraging in *T. o. luteola* and reflect their proclivity to forage on road-killed carrion, a behavior which likely increases turtle mortality on roads.

We thank Jon Erz and the Sevilleta National Wildlife Refuge for research access (special use permit 22522 08-018).

SQUAMATA — LIZARDS

***ACRITOSCINCUS PLATYNOTA* (Red-throated Skink). ENVIRONMENTALLY CUED HATCHING.** In some groups such as amphibians, embryos can choose a hatching date by assessing and responding to risks posed by abiotic or biotic factors (Warkentin and Caldwell 2009. *In* Dukas and Ratcliffe [eds.], Cognitive Ecology II. The Evolutionary Ecology of Learning, Memory and Information Use, pp. 177–200. Univ. of Chicago Press, Chicago, Illinois). Recent research and a review have established that environmentally cued hatching (ECH) occurs in reptiles (Doody 2012. Integr. Comp. Biol. 51:49–61). In one type of ECH, embryos hatch early in response to predator attacks (Warkentin and Caldwell, *op. cit.*). Although a few lizard species can hatch early in response to being handled, ECH is unknown for most lizard species, presumably due to the difficulty in finding lizard eggs (Doody et al. 2009. Quart. Rev. Biol. 84:229–252) and due to the lack of understanding of the adaptive context of hatching in response to handling (i.e., handlers assume that eggs hatching in hand reflects coincidence). Herein, we report on an observation of early hatching in *Acritoscincus platynota* from eastern Australia. We comment on implications for predator avoidance.

In March 2008 at around 1800 h, BS raked seven small skink eggs and one hatched eggshell from a sandy area under a large sandstone rock near Silverdale, New South Wales, Australia (33.905216°S, 150.611240°E). The eggs were gently picked up during which time a small slit appeared on one egg within 10 seconds. Within about 20 seconds an embryo burst through the slit and the hatchling immediately ran across BS's hand. The hatchling was easily confirmed as a Red-throated Skink, based on throat coloration. The remaining eggs were placed back in the sand under the rock.

Our report has two noteworthy implications. First, the nest complement of eight eggs is probably greater than the maximum clutch size in the species, suggesting that the nest was communal; communal nesting has been reported for the species (Doody 2006. Herpetofauna 36:23–24). Second, the handling-induced hatching in *A. platynota* likely reflects early hatching in response to an increase in perceived predation risk, as observed in another Australian skink, *Lampropholis delicata* (Doody and Paull 2013. Copeia 2013:160–165). This observation, along with a similar finding for *Carlia schmeltzii* (BS, unpubl. obs.), suggests that the behavior may be widespread in Australian skinks, or perhaps in skinks in general. Further research should investigate the temporal hatching window (plasticity in hatching age and developmental stage) and the potential predators of *A. platynota*, and how they might elicit early hatching in the species. A comparative study of ECH in skinks would determine if early hatching is an ancestral trait or if it has evolved multiple times within that group.

***ANOLIS CRISTATELLUS* (Puerto Rican Crested Anole). ABNORMAL DEWLAP COLOR.** *Anolis cristatellus* is native to Puerto Rico and has been introduced to Florida, USA (Krysko et al. 2003. Florida Sci. 66:74–79; Kraus 2009. Alien Reptiles and Amphibians: A Scientific Compendium and Analysis. Springer, Dordrecht, Netherlands. 563 pp.). Typical *A. cristatellus* dewlap color and pattern is yellow with orange borders. In Florida there are two distinct source populations from San Juan and Agua Claras/Ceiba, northeastern Puerto Rico, established in Key Biscayne, Florida and South Miami, Florida, respectively (Kolbe et al. 2012. Ecol. Evol. 2[7]:1503–1516).

On 13 January 2014 at 1109 h, an adult male *A. cristatellus* was observed at Fairchild Tropical Botanical Gardens, Miami Florida,

FIG. 1. Abnormal dewlap color and pattern in *Anolis cristatellus*.

USA (25.403°N, 80.163°W, WGS84; < 1 m elev.). This individual was caught using a noose by WAB, with dewlap subsequently assessed by JTS. This population of *A. cristatellus* corresponds to the population originating from Agua Claras/Ceiba, northeastern Puerto Rico (Kolbe et al., *op. cit.*). This individual had an abnormally colored dewlap, with a large proportion being gray (Fig. 1). Another individual was subsequently caught (~1113 h) which also exhibited gray on its dewlap, however with a lower proportion and a more patchy distribution. A total of ~30 *A. cristatellus* were caught during this time period, with no other lizards displaying this dewlap pattern. Extensive sampling of *A. cristatellus* in this area has been conducted by JTS and no other lizards with this abnormal pattern have been observed previously.

BECKLES,** Department of Biology, University of Miami, 1301 Memorial Drive, Coral Gables, Florida 33146, USA (e-mail: winterbeckles@gmail.com)

***ANOLIS SAGREI* (Brown Anole). *GOPHERUS POLYPHEMUS* BURROW COMMENSALISM.** *Anolis sagrei* is native to Cuba and the Bahamas, and has been introduced throughout many tropical and subtropical regions of the world (Kolbe et al. 2004. Nature. 431:177–181). In Florida, USA, *A. sagrei* has established invasive populations across much of the state and occurs in sympatry with native *Gopherus polyphemus* (Gopher Tortoise).

Gopherus polyphemus excavate burrows that are used as refuge sites by approximately 60 species of vertebrates and more than 300 species of invertebrates (Jackson and Milstrey 1989. *In* Diemer et al. [eds.], Proceedings of the Gopher Tortoise Relocation Symposium, pp. 86–98. Florida Game and Fresh Water Fish Commission, Tallahassee, Florida; Witz et al. 1991. Am. Midl. Nat. 126:152–158). We report observations of a previously unreported *G. polyphemus* burrow commensal species.

On three separate occasions during March 2014, we observed *A. sagrei* using *G. polyphemus* burrows as retreat sites on an island in the intracoastal waterway near Marineland, Florida, USA (29.6236°N, 81.2106°W; WGS84). All three *A. sagrei* were adults and two were identified as males based on size and dorsal pattern. One *A. sagrei* was observed basking at the mouth of a burrow at 1000 h on 8 March 2014. It likely used the burrow as a retreat site overnight and had emerged to bask in the sunlight. After photographing the lizard, it retreated about 0.25 m inside the burrow. At 1100 h on 25 March 2014, we observed another *A. sagrei* flee about 2 meters across the ground to a burrow and about 15 cm inside. At 1630 h on 25 March 2014, we observed an adult of unknown sex about 15 cm inside a burrow and oriented facing out of the burrow. The lizard retreated at least 1 m inside the burrow after our approach.

Each *A. sagrei* used a different burrow, which varied in size of opening (N = 3, width = 31.3 ± 2.3 cm, height = 11.0 ± 1.3 cm) and maintenance. Two contained leaves and twigs at the mouth of the burrow, one of which was partially collapsed. The third burrow appeared well maintained at the mouth, but had a 10 cm hole in the top of its tunnel about 0.5 m behind the mouth. We were unable to confirm if the burrows were being actively used by *G. polyphemus*.

Although *A. sagrei* occupy a wide range of habitats, they usually associate with arboreal and semi-arboreal structure. We are unaware of any previously published accounts of burrow use by *A. sagrei*. We provide evidence that *A. sagrei* use *G. polyphemus* burrows as retreat sites, but it is unclear how often this occurs and how *A. sagrei* might affect the ecology and community structure of *G. polyphemus* burrows.

***BASILISCUS PLUMIFRONS* (Double-Crested Basilisk Lizard). ANTAGONISTIC BEHAVIOR.** The Double-Crested Basilisk Lizard is widely distributed in the Caribbean lowlands of Central America from Nicaragua to Panama (Van Devender 1983. *In* D. Janzen [ed.], Costa Rican Natural History, pp. 378–380. Univ. Chicago Press, Chicago, Illinois). This species is considered a generalist feeder of invertebrates and vertebrates, in addition to various flowers and fruits (Guyer 1994. *In* McDade et al. [eds.], La Selva: Ecology and Natural History of a Neotropical Forest, pp. 210–261. Univ. Chicago Press, Chicago, Illinois; Marquis and Braker 1994. *In* McDade et al., *op. cit.*, pp. 261–281). Unlike other species in the genus, which primarily occupy water-margin habitats, *B. plumifrons* is often observed away from water (van Devender, *op. cit.*). Nothing has been published regarding the interaction of *B. plumifrons* at food sources with other vertebrates (such as birds) with similar diets.

On 10 February 2014, between 1500 h and 1600 h, several species of birds were observed feeding intermittently at a small pile of freshly peeled bananas placed on a wooden tray atop a post about 0.75 m above ground. The feeding station was in an open grassy area approximately 50 m upslope from the Sarapiqui River at La Virgen, Heredia Province, Costa Rica (10.38°N, 84.12°W) and at an elevation of about 200 m. This locality is within premontane tropical wet forest (Holdridge 1967. Life Zone Ecology. Tropical Science Center, San Jose, Costa Rica. 187 pp.). The actual study site is on the grounds of Centro Neotropico Sarapiquis (CNS) where the bird-feeding station has been in place several years.

During the single day of observing birds at the feeder, the following species were present: Clay-colored Robin (*Turdus grayi*), Summer Tanager (*Piranya rubus*), Blue-gray Tanager (*Thraysis episcopus*), Green Honeycreeper (*Chlorophantes spiza*), Shining Honeycreeper (*Cyaneges lucidus*), Passerinis/Cherries Tanager (*Ramphocelus costaricensis*), and Blue Dacnis (*Dacnis cayarea*). Up until 1500 h, the Clay-colored Robin appeared dominant at the bananas as it chased smaller birds whenever it appeared. This apparent dominance was episodic throughout the observation period.

At about 1500 h, a single adult male *B. plumifrons* suddenly appeared at the feeder, approaching from a small cluster of old citrus trees from a distance of about 15 m. At first, the lizard fed on a banana peel in the grass beneath the feeder, devouring the entire peel in about 12 minutes. The lizard's arrival coincided with the departure of all birds except the Clay-colored Robin. Upon finishing the banana peel, the lizard quickly jumped onto the feeder, remaining motionless there for about 10 minutes, and chasing away the Clay-colored Robin. After several minutes, the *B. plumifrons* commenced to devour the fruit on the tray. It fed intermittently in bouts of 2–4 minutes and shifted position on the tray three times. During this period, no birds shared the fruit station platform. At about 1530 h, a Clay-colored Robin landed on the grass near the feeder. It slowly circled around the feeder for a few minutes, flew up to the fruit, chased the *B. plumifrons*, and began to eat the fruit. Within a minute or two, other bird species began to reappear at the feeder. The *B. plumifrons* did not return for the rest of the day.

These observations, while limited, indicate an antagonistic interaction between a frugivorous bird and an omnivorous lizard at a long-standing artificially-placed fruit source. Furthermore, it is an example of one dominant feeder being aggressively replaced with another and then the reverse occurring as well. Both *B. plumifrons* and the Clay-colored Robin deploy a "surprise" tactic in displacing each other at this artificial food source, and perhaps also in nature. Furthermore, each animal invokes a skittish response mediated by visual stalking from the grass towards the feeding site. Local workers at CNS stated that they have observed *B. plumifrons* exhibiting similar behavior many times at the bird feeder. To my knowledge, this is the first report of *B. plumifrons* interacting with birds at a food source. Furthermore, it may demonstrate habituation by *B. plumifrons* to exploit a consistently available food source over time.

I thank Roberta Gordon for field assistance and the Milwaukee Public Museum and Tirimbina Rainforest Center for logistical support. Robert Henderson of the Milwaukee Public Museum kindly and thoughtfully reviewed the manuscript.

ALLEN M. YOUNG, Section of Invertebrate Zoology, Milwaukee Public Museum, 800 W. Wells Street, Milwaukee, Wisconsin 53233, USA; e-mail: young@mpm.edu).

***BRONCHOCELA CRISTATELLA* (Green Crested Lizard). REPRODUCTION.** *Bronchocela cristatella* ranges from the Nicobar Islands of India, eastward through Myanmar and Thailand and south through Peninsula Malaysia and Singapore, eastward through Papua, Indonesia (Diong and Lim 1998. Raffles Bull. Zool. 46:345–359; Hallermann 2005. Russian J. Herpetol. 12:168–183). There are reports on clutch sizes of 1–4 eggs (Das 2010. A Field Guide to the Reptiles of South-East Asia. New Holland Publishers, London, UK. 376 pp.); 1, 2 eggs (Manthey and Grossmann 1997. Amphibien & Reptilien Südostasiens. Natur und Tier – Verlag, Berlin. 512 pp.; Malkmus et al. 2002. Amphibians & Reptiles of Mount Kinabalu [North Borneo]. Koeltz Scientific Books, Königstein, Germany. 424 pp.); 2 eggs (Cox et al. 1998. A Photographic Guide to Snakes and other Reptiles of Peninsular Malaysia, Singapore and Thailand. New Holland Publishers Ltd, London, UK. 144 pp.). Grismer (2011. Lizards of Peninsular Malaysia, Singapore, and their Adjacent Archipelagos, Their Description, Distribution, and Natural History. Edition Chimaira, Frankfurt am Main. 728 pp.) suggested *B. cristatella* breeds year round. The purpose of this note is to report additional information on *B. cristatella* reproduction from a histological examination of museum specimens from West Malaysia.

TABLE 1. Monthly stages in the ovarian cycle of 20 adult *Bronchocela cristatella* from West Malaysia: * = 1 female with oviductal eggs was undergoing concurrent yolk deposition for a subsequent egg clutch.

Month	N	Quiescent	Yolk deposition	Enlarged follicles > 5 mm	Oviductal eggs
March	1	0	1	0	0
June	1	0	1	0	0
July	7	3	0	1	3
August	4	0	0	2	2*
September	6	2	2	1	1*
November	1	0	0	0	1*

A sample of 32 *B. cristatella* collected during 2002–2006 and 2008–2012 in West Malaysia deposited in the herpetology collection of La Sierra University (LSUHC), Riverside, California, USA, was examined. This series consisted of eleven males (mean SVL = 95.1 mm ± 11.2 SD, range = 73–111 mm), 20 adult females (mean SVL = 96.0 mm ± 7.3 SD, range = 84–109 mm) and one juvenile female (SVL = 72 mm). *Bronchocela cristatella* were collected in West Malaysian states: Johor (N = 14), Kedah (N = 3), Pahang (N = 3), Penang (N = 2), Perak (N = 3), Selangor (N = 5), Serak (N = 1), Terengganu (N = 1).

A cut was made in the lower abdominal cavity and the left testis or ovary was removed, embedded in paraffin, cut into 5 µm sections and stained with Harris hematoxylin followed by eosin counterstain. Enlarged follicles (> 5 mm) or oviductal eggs were counted. Histology slides were deposited in LSUHC.

Two stages were observed in the testicular cycle: 1) spermiogenesis, seminiferous tubules are lined by sperm, or clusters of metamorphosing spermatids; 2) regressed, seminiferous tubules are reduced in size and contain spermatogonia and interspersed Sertoli cells. Males were undergoing spermiogenesis in the following months: July (N = 3), August (N = 6), September (N = 1). One male of adult size (SVL = 94 mm) contained a regressed testis (LSUHC 5673). Our male sample sizes are too small to speculate on the significance of this single male with a regressed testis in the yearly male reproductive cycle. The smallest reproductively active male (spermiogenesis) measured 73 mm SVL (LSUHC 6543) and was collected in August.

Four stages were observed in the ovarian cycle (Table 1): 1) quiescent (no yolk deposition); 2) early yolk deposition (basophilic yolk granules in ooplasm); 3) enlarged pre-ovulatory follicles (> 5 mm); 4) oviductal eggs. Mean clutch size (N = 11) was an invariant 2.0. Three females (Table 1) with oviductal eggs were undergoing concurrent yolk deposition for a subsequent clutch indicating *B. cristatella* produces multiple clutches in the same year. The smallest reproductively active female exhibited yolk deposition, measured 84 mm SVL (LSUHC 10660), and was collected in June. One smaller female (SVL = 70 mm) had very small, inactive ovaries and was considered to be a juvenile (LSUHC 10647).

In conclusion, from the presence of female reproductive activity at opposite ends of the year it is apparent *B. cristatella* exhibits an extended reproductive cycle as do other lizards from southern Asia (see Inger and Greenberg 1966. J. Ecol. 47:1007–1021). Our report contains the first data indicating *B. cristatella* produces multiple clutches in the same year.

STEPHEN R. GOLDBERG, Natural History Museum of Los Angeles County, Herpetology Section, Los Angeles, California 90007, USA (e-mail: sgoldberg@whittier.edu); **L. LEE GRISMER,** La Sierra University, Department of Biology, Riverside, California 92515, USA (e-mail: lgrismer@lasierra.edu).

***COLEODACTYLUS MERIDIONALIS* (Meridian Gecko). HATCHLING MORPHOMETRICS.** *Coleodactylus* comprises a species complex of miniaturized diurnal leaf-litter inhabiting sphaerodactyl geckos (SVL 20–28 mm; Vanzolini 1968. Arq. Zool. 17:1–84; Avila-Pires 1995. Zool. Verh. 299:1–706). *Coleodactylus meridionalis* occurs in the Atlantic Forest, from the coastal Brazilian states to the more mesic, open formations from Ceará to Bahia (Vanzolini 1957. Pap. Avul. Zool. 13:1–17). Despite the broad geographic range of *C. meridionalis* (Ribeiro et al. 2013. Herpetol. Notes 6:23–27), the small size and cryptic habits have made the sphaerodactyl geckos the most poorly studied lizard group (Gamble et

al. 2011. Zool. J. Linn. Soc. 163:1244–1266). Here, we provide an observation of hatchling size in *C. meridionalis*.

At 1120 h on 2 February 2014, LBR and MLNS collected two eggs of *C. meridionalis* ca. 2 m apart among leaf litter at the Reserva Biológica de Serra Negra (8.6570144°S, 38.0263918°W, WGS84; elev. 1050 m), an Atlantic Forest enclave in the Caatinga formation in the municipality of Floresta, Pernambuco, Brazil. Each egg was placed in an eppendorf tube (2 mL) with a substrate of sand and leaf litter, and maintained at Laboratório de Morfofisiologia of the Núcleo de Ecologia Molecular (NECMOL) in the Centro de Conservação e Manejo de Fauna da Caatinga (CEMAFAUNA-CAATINGA) in Universidade Federal do Vale do São Francisco, Petrolina, Pernambuco. The eggs were kept in the laboratory at ambient temperature and humidity in the collection tubes.

On 15 March 2014 (42 days after collection), two juveniles emerged. Measurements were: SVL 10.6 ± 0.6 mm; tail length 8.2 ± 0.2 mm; forearm length 3.7 ± 0.4 mm; hind limb length 4.2 ± 0.1 mm; head length 4.0 ± 0.2 mm; head width 2.1 ± 0.1 mm; jaw length 2.3 ± 0.1 mm; head height 1.3 ± 0.1 mm; axilla–groin length 4.4 ± 0.9 mm; and mass 0.043 ± 0.001 g. *Coleodactylus meridionalis* has a single-egg clutch (Vanzolini et al. 1980. Répteis das Caatingas. Acad. Bras. de Ciênc. Rio de Janeiro, Brazil. 161 pp.), and this is the first record of hatchling size in this species. Lisboa et al. (2008. Herpetol. Rev. 39:221) reported the weight and size for one hatchling of the congeneric *C. natalensis*, born in a terrarium maintained in the laboratory: SVL 11 mm; tail length 0.8 mm; forearm length 3.1 mm; fourth finger 0.4 mm; hind limb length 3.6 mm; fourth toe 0.7 mm; head length 2.9 mm; head width 2.0 mm; jaw length 1.6 mm; head height 1.1 mm; body width 2.2 mm; pelvis width 1.3 mm; axilla-groin length 4.4 mm; and mass 0.024 g.

Specimens of *C. meridionalis* (MFCH 3521, 3522) were deposited in the Herpetological Collection of Museu de Fauna da Caatinga (MFCH), municipality of Petrolina. We thank the Instituto Chico Mendes de Conservação da Biodiversidade (ICMBio) for the collection permit (number 42485-2).

RIBEIRO, Universidade Federal do Vale do São Francisco – UNIVASF, Campus Ciências Agrárias, CEP 56300-990, Petrolina, Brazil; Centro de Conservação e Manejo de Fauna da Caatinga (CEMAFAUNA-CAATINGA), Universidade Federal do Vale do São Francisco – UNIVASF, Campus Ciências Agrárias, Rodovia BR 407, km 12, Lote 543, s/nº, C1, CEP 56300-990, Petrolina, Brazil (e-mail: leonardo.ribeiro@univasf.edu.br); **MARIA L. N. SILVA,** Universidade Federal do Vale do São Francisco – UNIVASF, Campus Ciências Agrárias, CEP 56300-990, Petrolina, Brazil.

***GONOCEPHALUS ABBOTTI* (Abbott's Anglehead Lizard). REPRODUCTION.** *Gonocephalus abbotti* extends from southern peninsular Thailand, southward through Peninsular Malaysia (Grismer 2011. Lizards of Peninsular Malaysia, Singapore and their Adjacent Archipelagos. Edition Chimaira, Frankfurt am Main. 728 pp.). To our knowledge, there is no published information on the reproduction of *G. abbotti*. In this note we present data on the first egg clutch known from *G. abbotti*.

One female *G. abbotti*, SVL = 153 mm, was collected 21 August 2003 in West Malaysia, Perak State, Temengor (5.6000°N, 101.3500°E) by LLG and deposited in the herpetology collection of La Sierra University (LSUHC), Riverside, California, USA, as LSUHC 5678. The body cavity was opened and the ovaries were examined. A total of seven enlarged follicles (> 9 mm) were observed. Four were on the left ovary, three were on the right ovary. Seven is the first clutch size recorded for *G. abbotti*.

STEPHEN R. GOLDBERG, Natural History Museum of Los Angeles County, Herpetology Section, Los Angeles, California 90007, USA (e-mail: sgoldberg@whittier.edu); **L. LEE GRISMER,** La Sierra University, Department of Biology, Riverside, California 92515, USA (e-mail: lgrismer@lasierra.edu).

***GONOCEPHALUS GRANDIS* (Giant Forest Dragon). REPRODUCTION.** *Gonocephalus grandis* ranges from southern Thailand throughout Peninsular Malaysia to Sumatra and Borneo (Manthey and Denzer 1991. Sauria 13:3–10). There are two reports of clutch size for *G. grandis*. Manthey and Grossmann (1997. Amphibien & Reptilien Südostasiens. Natur und Tier – Verlag, Münster. 512 pp.) reported clutches of one to six eggs; Hendrickson (1966. Bull. Nat. Mus. Singapore 34:53–71) recorded clutches of two to five eggs. In this note we present evidence that *G. grandis* produces multiple clutches in the same year.

Three female *G. grandis* (mean SVL = 115.0 ± 5.3 SD, range = 109–119 mm) were collected by LLG in West Malaysia, Perak State, Temengor (5.6000°N, 101.3500°E) and deposited in the herpetology collection of La Sierra University (LSUHC), Riverside, California, USA, as LSUHC 6692 (collected August 2004), 8188, 8197 (collected September 2006). The body cavity was opened and the ovaries were examined. All three females contained oviductal eggs, mean clutch size was 3.7 ± 0.58 SD, range = 3, 4. The left ovary of LSUHC 8188 and 8197 were removed, embedded in paraffin, histological sections were cut and stained with hematoxylin followed by eosin counterstain. Histology slides were deposited in LSUHC. The ovary of LSUHC 8188 in addition to oviductal eggs, exhibited concurrent yolk deposition for a subsequent clutch. No histology was performed on LSUHC 6692, which in addition to oviductal eggs, contained an enlarged (5 mm) follicle for a subsequent clutch. From the above observations, we conclude *G. grandis* produces multiple clutches in the same year.

STEPHEN R. GOLDBERG, Natural History Museum of Los Angeles County, Herpetology Section, Los Angeles, California 90007, USA (e-mail: sgoldberg@whittier.edu); **L. LEE GRISMER,** La Sierra University, Department of Biology, Riverside, California 92515, USA (e-mail: lgrismer@lasierra.edu).

***GONOCEPHALUS ROBINSONII* (Robinson's Anglehead Lizard). REPRODUCTION.** *Gonocephalus robinsonii* is endemic to Peninsular Malaysia (Grismer 2011. Lizards of Peninsular Malaysia, Singapore and their Adjacent Archipelagos. Edition Chimaira, Frankfurt am Main. 728 pp). There are reports of clutches of five to eight eggs in Manthey and Grossmann (1997. Amphibien & Reptilien Südostasiens. Natur und Tier – Verlag, Münster. 512 pp) and gravid females in July and August with clutches of five to seven eggs (Grismer, *op. cit.*). The purpose of this note is to report new information on *G. robinsonii* reproduction.

Two *G. robinsonii* females (mean SVL = 130.00 ± 12.7 SD, range = 121–139 mm collected in West Malaysia and deposited in the herpetology collection (LSUHC) of La Sierra University, Riverside, California, USA, as LSUHC 7233 collected March 2005 in Pahang State, Cameron Highlands (4.5000°N, 101.5000°E) and LSUHC 5873 collected June 2008 Pahang State, Selangor (3.3333°N, 101.5000°E) were examined. The left ovary of LSUHC 5873 was removed, embedded in paraffin, histological sections were cut at 5 µm and stained with bematoxylin followed by eosin counterstain. This histological slide was deposited in LSUHC.

A cut was made in the lower abdominal cavity and the ovaries were examined. LSUHC contained nine enlarged preovulatory

follicles (5 mm diameter). Nine is a new maximum clutch size for *G. robinsonii*. LSUHC 5873 contained six oviductal eggs. Beside oviductal eggs, follicles in the ovary of LSUHC 5873 exhibited concurrent yolk deposition indicating *G. robinsonii* may produce multiple clutches in the same reproductive season.

STEPHEN R. GOLDBERG, Whittier College, Department of Biology, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **L. LEE GRISMER,** La Sierra University, Department of Biology, Riverside, California 92515, USA (e-mail: lgrismer@lasierra.edu).

***LEPOSTERNON POLYSTEGUM*. ENDOPARASITES.** Biological aspects of amphisbaenians are poorly known when compared to other reptiles, mainly due to their fossorial habits (Gomes et al. 2009. J. Herpetol. 43:377–384; Filogonio et al. 2013. J. Helminthol. 87:135–140). Regarding parasitism, many studies have shown that amphisbaenians are common hosts of helminths, harboring specific genera of nematodes (Filogonio et al., *op. cit.*). One of these, the nematode genus *Paradollfusnema* Baker, 1982 comprises two species: *P. amphisbaenia,* known to infect *Leptosternon microcephalum* and *L. wuchereri* from Brazil; and *P. telfordi* described infecting *Rhineura floridana* from Florida, USA (Bursey 2002. J. Parasitol. 88:554–556; Ribeiro et al. 2011. J. Herpetol. 6:177–188). *Paradollfusnema amphisbaenia* is a cosmocercid nematode recorded in northeastern and southeastern Brazil (Ávila and Silva 2010. J. Venom. Anim. Toxins. Incl. Trop. Dis. 16:543–572; Filogonio et al., *op. cit.*).

Herein, we report *P. amphisbaenia* infecting *L. polystegum* in northeastern Brazil. On 2 September 2012 an adult individual of *L. polystegum* was collected by pitfall trap in Pinheiros farm, municipality of Barbalha (7.363846°S, 39.339514°W; WGS84), state of Ceará, Brazil. The *L. polystegum* specimen was euthanized, fixed with 10% formalin, and deposited at the Coleção Herpetológica da Universidade Regional do Cariri (URCA-H 3901). The body cavity, esophagus, stomach, lungs, small and large intestines were opened and separately examined for helminths under a stereomicroscope. Endoparasites were cleared in phenol, identified, and deposited in the Coleção Parasitológica da Universidade Regional do Cariri, Brazil (URCA-P 419). Four adult *P. amphisbaenia* (two males and two females) were found in the large intestine. Infection by helminths has been reported only for *Leposternon microcephalum* and *L. wuchereri* (Ávila and Silva, *op. cit.*; Ribeiro et al., *op. cit.*; Filogonio et al., *op. cit.*). Thus, *Leposternon polystegum* represents a new host record and Ceará state a new locality record for *P. amphisbaenia*.

We are grateful to Mr. Renato Salvação for allow the study at Sítio Pinheiros. To Conselho Nacional de Desenvolvimento Científico e Tecnológico—CNPq for a fellowship to CFS and for financial support (process 475107/2011-0). To Coordenação de Aperfeiçoamento de Pessoal de Nível Superior—CAPES to a master fellowship to CFS and RHO and to Fundação Cearense de Apoio ao Desenvolvimento Científico e Tecnológico—FUNCAP for a research Grant awarded to RWA (BPI-0067-00006.01.00/12).

***LIOLAEMUS PACHA*. DIET.** The Neotropical lizard *Liolaemus pacha,* previously known as *L. quilmes* (Etheridge 1993. Boll. Mus. Reg. Sci. Nat. Torino 11:137–199; Heredia et al. 2013. Zootaxa 3681:524–538), belongs to the *L. darwinii* group, and is one of more than 250 species attributed to this genus (Abdala and Quinteros 2014. Cuad. Herpetol. 28[2]: *in press*). *Liolaemus* species show a great variety of habitat preferences, reproductive strategies, and feeding habits. *Liolaemus pacha* is found at "Los Cardones" (26.6670°S, 65.8180°W, WGS84; elev. 2725 m), Tucumán province, Argentina.

Halloy et al. (2006. Rev. Esp. Herpetol. 20:47–56) found that *L. pacha* was primarily insectivorous, eating mainly ants (Hymenoptera: Formicidae) but also insects from the orders Hemiptera (Heteroptera) and Coleoptera. The authors also reported the presence of unidentified plant material in one male. We filmed individuals of this species with a digital camera (Sony HDR-Cx290) in natural habitat for two years (from September 2012 to March 2014) as part of another behavioral study. During this time we recorded two females and two males, all adults, actively eating sprouts of *Portulaca cf. fulgens* Griseb. (Portulacaceae) and *Amicia medicaginea* Griseb. (Fabaceae). The first two foraging episodes occurred 10 February 2013 at 1115 h and the second two occurred 16 January 2014 between 1130 h and 1200 h. Plant consumption has been reported in another species of the *L. darwinii* group, *L. crepuscularis* (Semhan et al. 2013. South Am. J. Herpetol. 8[2]:102–108), although the plant material could not be identified. Species not belonging to this group have also been reported to eat plants, among these: *Adesmia horrida*, *Hoffmannseggia minor,* and *Glandularia microphylla* in *L. poecilochromus* (Valdecantos et al. 2012. Copeia 2012:204–211); and *Lycium*, *Atriplex*, *Larrea*, and *Portulaca* in *L. cuyanus* (Moreno Azócar and Acosta 2011. J. Herpetol. 45[3]:283–286).

We thank Stéphan Halloy for his help in identifying the plants, CONICET, National Scientific and Technical Research Council, for a scholarship to NV, and Natural Resources and Soils of the Tucumán province for permission to work in the field (permit 539-RN).

***LIPINIA VITTIGERA* (Yellow-striped Tree Skink). REPRODUCTION.** *Lipinia vittigera* ranges from southern Myanmar, Thailand, Cambodia, and Laos through the Malay Peninsula to Singapore and Sumatra into northern Borneo (Grismer 2011. Lizards of Peninsular Malaysia, Singapore and their Adjacent Archipelagos. Edition Chimaira, Frankfurt am Main, Germany. 728 pp.). Grismer (*op. cit.*) reported gravid females during March and hatchlings in July. Das (2010. A Field Guide to the Reptiles of South-East Asia. New Holland Publishers, Ltd, London, United Kingdom, 376 pp.) reported *L. vittigera* is oviparous and produces clutches of 2–4 eggs. The purpose of this note is to provide additional information on the reproductive biology of *L. vittigera* from a histological examination of gonadal material.

A sample of nine *L. vittigera* from West Malaysia collected 2003–2006, 2010, 2012 by LLG and deposited in the herpetology collection of La Sierra University, California, USA (LSUHC) was examined. The sample consisted of two adult males (SVL = 34 mm, five adult females (mean SVL = 38.0 mm ± 2.0 SD, range = 35–40 mm), and two subadults (mean SVL = 27.5 mm ± 6.4

SD, range = 23-32 mm) collected in: Johor LSUHC 8211; Kedah LSUHC 10600; Pahang LSUHC 4417, 5148, 5175, 6126, 7254; Penang LSUHC 9991, 9992.

A cut was made in the lower abdominal cavity and the left testis or ovary was removed, embedded in paraffin, cut into 5-µm sections and stained with Harris hematoxylin followed by eosin counterstain. Enlarged follicles > 3 mm were counted. Histology slides were deposited at LSUHC.

Two males (one each from February and September) were undergoing spermiogenesis with seminiferous tubules lined by sperm or clusters of metamorphosing spermatids. Five mature females were collected in February to March. Four contained enlarged ovarian follicles > 3 mm. Mean clutch size (N = 4) was 1.5 ± 0.58, range = 1, 2. The remaining adult female exhibited yolk deposition with the ooplasm containing vitellogenic granules. A smaller female from April (SVL = 32 mm) contained tiny ovaries and was considered a subadult. A presumed neonate from June measured 23 mm SVL. The presence of males undergoing spermiogenesis in widely separated months (February and September) suggests *L. vittigera* has an extended reproductive cycle. One is a new minimum clutch size for *L. vittigera.*

STEPHEN R. GOLDBERG, Whittier College, Department of Biology, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **L. LEE GRISMER,** La Sierra University, Department of Biology, Riverside, California 92515, USA (e-mail: lgrismer@lasierra.edu).

***OPHISAURUS VENTRALIS* (Eastern Glass Lizard). PREDATION.** Herein we report the first known predation on *Ophisaurus ventralis* by a Coyote (*Canis latrans*). Coyotes are opportunistic predators known to utilize a wide range of prey (Leopold and Krausman 1986. J. Wildl. Manage. 50:290–295; Grigione et al. 2011. Urban Ecol. 14:655–663). We conducted necropsies and analyzed stomach contents of 234 Coyotes collected October 2011–March 2014 throughout Florida, USA. The stomach from an 8.17 kg male collected on 12 September 2013 at Naval Air Station Pensacola, Escambia Co., contained the intact skin of an *O. ventralis* and other items.

***PHRYNOSOMA MCALLII* (Flat-tailed Horned Lizard). LATE SEASON COURTSHIP BEHAVIOR.** *Phrynosoma mcallii* is a small phrynosomatid with a distinct dark mid-dorsal stripe, double row of fringe scales on its sides, and two median long horns (Brennan and Holycross 2006. A Field Guide to Amphibians and Reptiles in Arizona. Arizona Game and Fish Department, Phoenix, Arizona. 150 pp.). This species has one of the smallest distributions of any horned lizard. It is found in desert areas of Sonora and Baja California, Mexico, and in the United States in southeastern California and extreme southwestern Arizona (Sherbrooke 2003. Introduction to the Horned Lizards of North America. University of California Press, Berkeley. 178 pp.). Here, we describe behavior observed in the late summer of 2013 that was suggestive of late season reproduction in *P. mcallii.*

Mating of *P. mcallii* is thought to occur in May and June (Rorabaugh and Young 2009. *In* Jones and Lovich [eds.], Lizards of the American Southwest, pp. 182–185. Rio Nuevo Publishing, Tucson, Arizona). However, Barrows and Allen (2009. Southwest. Nat. 54:307–316) reported on breeding behavior for *P. mcallii* through the end of August in the Coachella Valley, California 2000–2003. Further, late-season hatching pulses for *P. mcallii* were speculated by Barrows and Allen (*op. cit.*) to not be associated with rainfall patterns.

FIG. 1. Adult *Phrynosoma mcallii* engaging in late-season breeding behavior south of Yuma, Arizona.

On 30 August 2013, we observed two Flat-tailed Horned Lizards displaying courtship behavior in the Yuma Desert ~ 30 km S of Yuma, Arizona, USA (32.45°N, 114.57°W; WGS84). The two lizards (male SVL = 68 mm; mass = 9.0 g; and female SVL = 65; mass = 12.5 g) were initially observed from a distance of 5 m bobbing up and down. We approached the lizards and were able to obtain video (available upon request) and still photos of the event (Fig. 1). The male lizard had its upper right leg over the female's back and was biting the two left side horns, which protrude from the back of the female's head. During this time the female was slowly moving her tail side to side in the sand demonstrating typical bobbing movements with her rear left leg over the back of the male. After five minutes of observation we picked the lizards up and weighed and measured them before releasing them. After release, the female approached the male posturing her tail upwards with her cloaca facing his nostrils (vent flash). He then licked the skin near the vent (vent lick). This continued for a few more minutes before we retreated from the area.

These activities were indicative of late-season mating behavior, which has not been reported for this location and is not well understood for this lizard in general.

WOODROW L. CRUMBO (e-mail: wcrumbo@azgfd.gov), and **DANIEL J. LEAVITT** (e-mail: dleavitt@azgfd.gov), Arizona Game and Fish Department, 5000 West Carefree Highway, Phoenix, Arizona 85086, USA.

***PTYCHOZOON INTERMEDIUM* (Philippine Flying Gecko). AVIAN PREDATION.** *Ptychozoon intermedium* is a large gecko (82.4–99.8 mm SVL) occurring on the islands of Mindanao, Maripipi, Dinagat, and Leyte, Philippines (Brown et al. 1997. Herpetologica 53:357–373). Fieldworkers seldom encounter this Philippine endemic gecko, presumably due to its cryptic coloration, arboreal habit, and preferred canopy microhabitat (Brown and Diesmos 2000. Slyvatrops 10:107–124). Here we report observed predation on *P. intermedium* by the Mindanao Lowland Scops Owl (*Otus everetti*).

FIG. 1. A Mindanao Lowland Scops Owl (*Otus everetti*) preying upon a Philippine Flying Gecko *(Ptychozoon intermedium*) on Mindanao Island, Philippines.

At 1830 h on 20 March 2014, during a birdwatching trip in Barangay Tabon, Bislig City, Surigao del Sur Province, Mindanao Island, Philippines (8.246033°N, 126.278503°E, WGS84; elev. 109 m), CF observed an owl perched on a bamboo stalk responding to a birdcall produced by a forest guide. In its beak, the owl carried an adult *P. intermedium* by the neck (Fig. 1). The left side of the gecko's body had a puncture wound with visibly everted viscera. The incident was observed for ca. three minutes before the owl flew to another location, thus the actual consumption of the gecko was not observed. To our knowledge, this is the first documented record of avian predation on flying geckos. Photographic vouchers were deposited at the Lee Kong Chian Natural History Museum, National University of Singapore, (ZRC[IMG] 2.223a–d).

We thank Rafe M. Brown for providing references and comments on this note and Kelvin K. P. Lim for ZRC voucher numbers.

EMERSON Y. SY, Philippine Center for Terrestrial and Aquatic Research, 1198 Benavidez St., Unit 1202, Tondo, Manila, Philippines (e-mail: emersonsy@gmail.com); **CON FOLEY**, Con Foley Photography, 60 Havelock Road #03-29 Singapore 169658 (e-mail: con@confoley.com); **ROMMEL M. CRUZ**, Birdwatch Palawan Ornithological Society, Pineda Rd., Madarcos Subdivision, San Pedro, Puerto Princesa City, Palawan 5300, Philippines.

***SCELOPORUS ANGUSTUS* (Santa Cruz Island Sator). REPRODUCTION.** *Sceloporus angustus* is known only from Islas San Diego and Santa Cruz in the Gulf of California where it is ubiquitous (Grismer 2002. Amphibians and Reptiles of Baja California Including Its Pacific Islands and the Islands in the Sea of Cortés. Univ. of California Press, Berkeley. 399 pp.). Grismer (*op. cit.*) proposed that the reproductive season extended through spring and summer based on the presence of bright female coloration during these periods. Clutches consisted of five to seven eggs. The purpose of this note is to present additional information on *S. angustus* reproduction from a histological examination of museum specimens.

A sample of 13 *S. angustus* consisting of six adult males (mean SVL = 78.2 mm ± 7.8 SD, range = 65–86 mm), five adult females (mean SVL = 62.8 mm ± 2.0 SD, range = 61–66 mm), one juvenile male (SVL = 61 mm) and one juvenile female (SVL = 53 mm) from Isla Santa Cruz, Baja California Sur, Mexico was examined from the herpetology collections of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA, LACM 134740, 134741, 134743, 134750, 134753–134755 and the University of Colorado Museum of Natural History (UCM), Boulder, Colorado, USA, UCM 26059, 26063, 26064, 26066–26068. Lizards were collected in May 1982 (LACM) and August 1964 (UCM).

A cut was made in the lower abdominal cavity and the left testis or ovary was removed, embedded in paraffin, cut at 5 µm, and stained with Harris hematoxylin followed by eosin counterstain. Oviductal eggs were counted. No histology was performed on them. Histology slides were deposited at LACM or UCM.

Two stages were observed in the testicular cycle: 1) recrudescence, proliferation of germ cells for the next period of spermiogenesis; 2) spermiogenesis, seminiferous tubules are lined by sperm or clusters of metamorphosing spermatids. Three males from May and two from August were undergoing spermiogenesis. The smallest reproductively active male (spermiogenesis) measured 65 mm (UCM 26067) and was collected in August. One larger male from May (SVL = 78 mm) exhibited recrudescence with spermatogonia and primary spermatocytes present. A smaller male (SVL = 61 mm) was undergoing an earlier stage of recrudescence (spermatogonia, no primary spermatocytes) and was considered to be a subadult.

Three stages were observed in the ovarian cycle: 1) quiescent (no yolk deposition); 2) early yolk deposition (basophilic vitellogenic granules in the ooplasm); 3) oviductal eggs. The smallest reproductively active female (early yolk deposition) measured 61 mm SVL (UCM 26066) and was collected in August. Two females from May exhibited quiescent ovaries. Two females from August exhibited early yolk deposition. One female (UCM 26064) contained four oviductal eggs. One smaller female (UCM 26059) from August measured 53 mm SVL, contained tiny ovaries and was considered a subadult. Histological findings of males undergoing spermiogenesis in May and August support the observations of Grismer (*op. cit.*) that *S. angustus* has an extended reproductive season that includes spring and summer. Four is a new minimum clutch size for *S, angustus*

I thank G. Pauly (LACM) and Emily Braker (UCM) for permission to examine *S. angustus*.

STEPHEN R. GOLDBERG, Whittier College, Department of Biology, Whittier, California 90608, USA; e-mail: sgoldberg@whittier.edu.

***SCELOPORUS ARENICOLUS* (Dunes Sagebrush Lizard). ACTIVITY PATTERNS AND FORAGING MODE.** Efforts have been made to gain a greater understanding of lizard activity patterns and foraging modes (Cooper 2005. Herpetol. Rev. 36:367–369). Lizard activity patterns influence our ability to detect them on the landscape and this is inextricably linked to how monitoring efforts are implemented to ensure proper stewardship. Foraging modes are indicative of energetic needs and are often

evaluated in models used to assess biophysical interactions between lizards and their landscapes. Here we describe the activity patterns and foraging mode of a small population (N = 10) of *S. arenicolus* from New Mexico, USA, to contribute to a growing understanding of the place of this lizard within the ecosystem.

Cooper et al. (2005. Herpetologica 61:250–259) described the activity and foraging mode of a small population of *S. arenicolus* from the Mescalero Sands of Chaves Co., New Mexico, USA. They report movements per minute (MPM) for *S. arenicolus* with a relatively high standard error (MPM: 0.80 ± 0.42). In 2010, we conducted 10 observations of individual *S. arenicolus* from Lea Co., New Mexico using a different methodology. Cooper et al. (*op. cit.*) described that they approached lizards and then began their observations. In contrast, we positioned ourselves in folding chairs at prominent places above sand-dune blowouts and waited to observe lizards. Once a lizard was spotted we recorded our data following the methods described by Cooper (*op. cit.*). In brief, these methods estimate MPM and percent time moving (PTM). Between 6 and 20 June 2010 we conducted observations at three separate locations within Lea Co., New Mexico. We measured substrate temperature (T_s) and air temperature (T_a) using a quick-read Schultheis thermometer (Miller & Weber, Inc. Ridgewood, New York) at the beginning of each observation. We recorded behavior for 10-minute intervals, with the exception of one 6-minute observation, for each lizard and categorized behavior as basking, feeding, or moving. We observed lizards with binoculars at a distance of more than 10 m.

Six male and four female *S. arenicolus* were observed for an average of 10:02 minutes per lizard. Observations occurred while T_s was 33.2 ± 0.79°C and T_a was 32.5 ± 0.75°C. During these observations, *S. arenicolus* were not very active (MPM = 0.35 ± 0.11; PTM = 0.01 ± 0.005). Two of the lizards were observed foraging on ants within blowouts. The majority of other lizards were observed basking either beneath shade of Shinnery Oak (*Quercus havardii*) or in direct sunlight. Our numbers are much lower than those reported by Cooper et al. (*op. cit.*) and probably reflect a more realistic value for an undisturbed *S. arenicolus*. This species is the subject of conservation action in both New Mexico and Texas and is threatened with landscape fragmentation (Leavitt and Fitzgerald 2013. Ecosphere 4:97). As such, data regarding their activity patterns will be valuable for conservation practitioners required to establish monitoring guidelines. We recommend that any methods utilized to monitor this species account for its low activity pattern and its ability to avoid being detected.

DANIEL J. LEAVITT, Arizona Game and Fish Department, 5000 West Carefree Highway, Phoenix, Arizona 85086, USA (e-mail: dleavitt@azgfd.gov); **MATTHEW R. ACRE**, Texas Tech University, Department of Natural Resources Management, Lubbock, Texas 79409-2120, USA.

***SCELOPORUS OCHOTERENAE*. PREDATION.** The predation of reptiles by birds is well documented and has been reported several times (e.g., Sandoval et al. 2008. Wilson J. Ornithol. 120[1]:214–216). Here we report the predation of *Sceloporus ochoterenae* by an adult male *Crotophaga sulcirostris* (Groove-billed Ani), which to our knowledge has not been previously recorded. This species of bird feeds principally on arthropods, mainly medium-sized grasshoppers and spiders, but also other arthropods as well as *Anolis* lizards (Payne 1997. *In* del Hoyo et al. [eds.], Handbook of the Birds of the World. Vol. 4. Sandgrouse to Cuckoos, pp. 508–607. Lynx Edicions. Barcelona, Spain). During April 2014, we conducted fieldwork studying birds and reptiles at Papalutla, municipality of Copalillo, Guerrero, México (18.012683°N, 98.567821°W, WGS84; 670 m elev.), located in a tropical dry forest near the Balsas River. We collected an adult Groove-billed Ani (total length 355 mm; mass 84 g) using a mist net (ornithological collection MZFC-ALTBAL 095). We found two partially digested adult *Sceloporus ochoterenae* (each with total length > 80 mm) in the gizzard of the bird, occupying ca. 80% of the total volume (Fig. 1). We identified the lizard species by the scales and the color pattern of the dorsum. This observation is the first predation event reported between this bird and *S. ochoterenae*.

FIG. 1. Two partially digested adult lizards of *Sceloporus ochoterenae*.

We thank Alfonso G. Navarro Sigüenza for logistic support provided through CONACyT 152060 project and Mrs. Juan Esteban Flores and Justino Morales for the facilities.

***SCELOPORUS UNIFORMIS* (Yellow-backed Spiny Lizard). LIFE HISTORY.** Limited information is available on *Sceloporus uniformis*, formally *S. magister uniformis* (Schulte et al. 2006. Mol. Phylog. Evol. 39:873–880), within the Virgin River Basin in Utah, Arizona, and Nevada, USA. We report on the morphology and activity of 210 captures of 132 individual *S. uniformis* along the lower Virgin River from St. George, Utah (37.0904°N, 113.5354°W; NAD83) to Gold Butte in Clark Co., Nevada (36.5667°N, 114.3333°W). We captured lizards from late May to early August from 2009 to 2013 to examine the effects of Saltcedar (*Tamarix* spp.) biocontrol and riparian restoration on herpetofauna communities (Bateman and Ostoja 2012. Anim. Conserv. 15:294–304). We established 21 trap arrays in riparian habitat with Saltcedar, Cottonwood (*Populus fremontii*), Willow (*Salix* spp.), Mesquite (*Prosopis* spp.), and Russian Olive (*Elaeaganus agustifolia*) trees.

TABLE 1. Morphological characteristics of *Sceloporus uniformis* captured during 2009–2013 from riparian habitat along the lower Virgin River in Nevada, Arizona, and Utah. Data are summarized by captures of individuals ≤ 39 mm SVL (hatchling), 40–79 mm SVL (juvenile), and ≥ 80 mm SVL (adult). Individuals may be present in multiple size classes, though measurements for recaptured individuals were averaged within size class.

Sex	N	SVL Mean (±SE) Range (mm)	VTL Mean (±SE) Range (mm)	Mass Mean (±SE) Range (g)
Hatchling (≤ 39 mm SVL)				
Female	10	34.6 (±1.1) 32–39	45.4 (±2.8) 27–57	1.2 (±0.1) 1–2
Male	5	34.2 (±1.5) 30–38	46.8 (±1.4) 44–51	1.3 (±0.2) 1–2
Unknown	4	33.5 (±1.5) 32–38	47.8 (±2.6) 42–53	1.0 (±0.0) 1
Juvenile (40–79 mm SVL)				
Female	24	71.4 (±1.1) 61–79	95.6 (±3.0) 51–110	11.8 (±0.5) 6–16
Male	21	73.0 (±1.1) 51–79	100.3 (±3.5) 44–118	13.0 (±0.6) 5–19
Adult (≥ 80 mm SVL)				
Female	31	88.0 (±1.0) 80–100	107.5 (±4.0) 40–134	24.2 (±1.3) 16–43
Male	45/45/42	93.3 (±1.3) 80–114	116.5 (±3.7) 28–154	29.5 (±1.5) 13.5–51

Sceloporus uniformis were captured with pitfall traps (51.9%), funnel traps (47.6%), and by hand along drift fences (0.5%). Snout–vent length (SVL), vent–tail length (VTL), mass, and sex were recorded for each capture (Table 1). When sex was difficult to determine (i.e., hatchlings due to their small size), sex was marked as unknown. Size classes were separated based on natural breaks in the data and results from primary literature (Tinkle 1976. Herpetologica 32:1–6; Goldberg 2012. Bull. South. California Acad. Sci. 111:25–28). Hatchlings became active towards the latter half of July with the earliest capture occurring on 16 July 2009. At higher elevations along the Virgin River, Tinkle (*op. cit.*) first observed hatchlings in Utah during early August; however, our first hatchling was captured in Utah on 24 July 2013. Juvenile and adult activity, in terms of total captures, peaked in the latter half of June and first half of July, respectively. Of the total number of juvenile captures, 10.2% (mean SVL = 69.1 mm, range = 51–77 mm, N = 9) occurred from 21–31 May, 23.9% (mean SVL = 71.4 mm, range = 59–79 mm, N = 21) from 1–15 June, 34.1 % (mean SVL = 72.2 mm, range = 59–79 mm, N = 30) from 16–30 June, 19.3% (mean SVL = 73.8 mm, range = 67–79 mm, N = 17) from 1–15 July, and 13.6% (mean SVL = 73.6 mm, range = 69–78 mm, N = 12) from 16–31 July. Of the total number of adult captures, 10.8% (mean SVL = 86.5 mm, range = 84–99 mm, N = 11) occurred from 21–31 May, 11.8% (mean SVL = 90.6 mm, range = 80–102 mm, N = 12) from 1–15 June, 27.5% (mean SVL = 93.4 mm, range = 80–111 mm, N = 28) from 16–30 June, 29.4% (mean SVL = 89.9 mm, range = 80–114 mm, N = 30) from 1–15 July, and 20.6% (mean SVL = 90.5 mm, range = 80–102 mm, N = 21) from 16–31 July. Overall, 28.8% (38 of 132) of marked lizards were recaptured during the study.

We acknowledge the Bureau of Land Management in Nevada and the Arizona Strip District, Clark County Public Works, and Utah Division of Wildlife Resources for permitting access to study sites. Scientific collecting permits were issued by the Arizona Game and Fish Department, Nevada Department of Wildlife, Utah Division of Wildlife Resources, and Institutional Animal Care and Use Committee. This study was funded by the Bureau of Reclamation Southern Rockies Landscape Conservation Cooperative (LCC) and Desert LCC.

***TROPIDOPHORUS MISAMINIUS* (Misamis Water Skink). NOVEL MICROHABITAT.** *Tropidophorus misaminius* is a large-sized (90–112 mm SVL) endemic water skink known to occur on Mindanao, Camiguin, and Basilan Island, Philippines. The species is usually found in rocky beds and banks of forest streams and occasionally in moist soil and under rotting logs in forests (Brown and Alcala 1980. Philippine Lizards of the Family Scincidae. Silliman University Press. Dumaguete City, Philippines. 264 pp.).This note reports on a novel microhabitat of *T. misaminius* on Mindanao.

At 1200 h on 30 January 2014, five adult *T. misaminius* were observed resting on the bank of a cave stream ca. 12 m into Okbot Cave, Sitio Sambayon, Barangay Suaon, Municipality of Kapalong, Davao del Norte Province, Mindanao Island, Philippines (7.745783°N, 125.667450°E, WGS84; 250 m elev.). To our knowledge, this is the first report of a *Tropidophorus* species utilizing a cave system as microhabitat (Fig. 1) (Ngo et al. 2000. Russian J. of Herpetol. 7:155–158; Honda et al. 2005. Zool. Scrip. 35:85–95; Ziegler et al. 2005. Salamandra 41:137–146; Nguyen et al. 2010. Zoosyst. Evol. 86:5–19). Photographic vouchers were deposited at the Lee Kong Chian Natural History Museum, National University of Singapore (ZRC[IMG] 2.220a–c).

FIG 1. Adult *Tropidophorus misaminius* near a cave stream 12 m from the entrance.

***UTA STANSBURIANA* (Side-blotched Lizard). PREFERRED BODY TEMPERATURE.** Many species of reptiles use behavioral means to thermoregulate, such as shuttling between patches of vegetation with different thermal characteristics (Cowles and Bogert 1944. Bull. Am. Mus. Nat. Hist. 83:261–296). Moreover, the preferred body temperature (T_p) that a lizard voluntarily selects in a laboratory thermal gradient provides a reasonable estimate of what a lizard would attain in the wild with a minimum of associated costs in the absence of constraints (biotic and abiotic factors) for thermoregulation (Huey and Slatkin 1976. Quart. Rev. Biol. 51:363–384; Pough and Gans 1982. *In* Gans and Pough [eds.], Biology of the Reptilia, Vol. 12, pp. 17–23. Academic Press, New York). *Uta stansburiana* is widely distributed across many habitats in western North American deserts from Baja California, Mexico north to the Columbia Plateau of Washington, USA (Lemos-Espinal and Smith 2007. Anfibios y Reptiles del Estado de Chihuahua, México / Amphibians and Reptiles of the State of Chihuahua, Mexico. UNAM-CONABIO, Mexico, D.F. 613 pp.). There have been many reports detailing thermal ecology in *U. stansburiana* in different environments (Waldschmidt and Tracy 1983. Ecology 64:476–484; Huey and Pianka 2007. Am. Nat. 170:473–478; Clarke and Zani 2012. J. Exp. Biol. 215:1117–1127). However data of preferred body temperature of *U. stansburiana* are rare (Sartorius et al. 2002. Can. J. Zool. 80:1966–1976) and in northern Mexico do not exist. Here, we describe thermal preference in *U. stansburiana* under laboratory conditions.

During June 2010, we conducted fieldwork in Samalayuca Dunes (31.4786°N, 106.4755°W, WGS84; 1180 m elev.) located in a mesquite-stabilized sand hummocks about 24 miles south of Ciudad Juarez, Municipality Juarez, Chihuahua, Mexico. The data presented are based on 16 adults (> 40 mm SVL; 8 females and 8 males) of *U. stansburiana* captured by noose.

All lizards were placed in a laboratory thermal gradient to obtain the T_p range. The thermal gradient consisted of a wooden shuttle box of 150 × 100 × 80 cm (length, width and height) divided into ten tracks with insulation barriers to prevent behavioral influence of adjacent lizards, and filled with 2–3 centimeters of sandy soil. The shuttle box was housed in a room with air conditioning at a constant temperature of 20°C. At one end, and at the center of the box, lamps were placed at different heights to generate a thermal gradient from 20–50°C. Lizards remained in the gradient from 700 to 2000 h; body temperature data were registered every hour starting at 800 h and using a digital thermometer Fluke model 51-II. The 25% and 75% quartile T_p range (T_{p25} and T_{p75}) of each species were calculated to obtain the lower and upper limit (Van Damme et al. 1990. Oikos 57:61–67; Herts et al. 1993. Am. Nat. 142:796–818). After laboratory experiments, all lizards were released at respective capture sites. We applied a nonparametric Kruskal-Wallis one way test to analyze differences between all measurements of body temperature in the laboratory and we used a Mann-Whitney Rank test to analyze the differences between gender.

There were no statistically significant differences between measurements of temperature ($H_6 = 5.000$, $p = 0.416$) or between gender ($U = 79.5$, $p > 0.05$). Mean preferred body temperature was 33.1°C (SD = 3.2, range = 25.5–38.0°C). Interquartile of 25% and 75% was 32.0°C and 35.2°C, respectively. These results suggest *U. stansburiana* can be considered a eurythermic species due to the wide range of T_p in this species. Future research should evaluate the species thermal efficiency by monitoring mean thermal requirements and microhabitat temperatures across its distribution to understanding effects of global warming on this geographically widespread lizard.

***VARANUS MITCHELLI* (Mitchell's Water Monitor). PREDATION.** Raptors likely regulate some reptile populations because the former are key predators of the latter. Although raptors generally take larger prey for their body size than other birds (Slagsvold and Sunerud 2007. J. Avian Biol. 38:650–661), large prey items can still be infrequent enough to go undetected in dietary studies based on stomach contents, regurgitated pellets, or scats. This is particularly true in the tropics, where the diet of raptors is understudied (e.g., Rangel-Salazar and Enriquez-Rocha 1993. J. Raptor Res. 27:121–122). Thus, observations of raptors preying upon medium to large reptiles in the tropics are an invaluable supplement to our knowledge of trophic interactions that may drive predator-prey interactions of reptiles and raptors. Herein I describe an observation of apparent predation of a Mitchell's Water Monitor by a Little Eagle (*Hieraaetus morphnoides*).

At ~1630 h on 16 February 2014 I spotted a Little Eagle perched about 5 m above ground in a paperbark tree (*Melaleuca* spp.) along the Margaret River, in tropical Western Australia (18.217097°S, 125.863506°E). As I approached to within 15 m the eagle took flight with an adult Mitchell's Water Monitor in its talons. The monitor was identifiable by its markings, coloration, shape and size. The eagle flew out of sight with the lizard; the limp appearance of the lizard indicated that it was dead. The observation occurred during the wet season, but the weather was mostly clear with an air temperature of 34°C.

My observation likely reflected predation, because Little Eagles rarely scavenge (Olsen et al. 2010. J. Raptor Res. 44:50–61). Reptiles vary in their importance as prey for Little Eagles, ranging from 2–82% depending on region (Aumann 2001. Wildl. Res. 28:379–393; Olsen et al. *op. cit.*). The other reported aerial predator of *V. mitchelli* is the Collared Sparrowhawk (*Accipiter cirrocephalus*) (Schultz and Doody 2004. *In* Pianka and King [eds.], Varanoid Lizards of the World, pp. 416–422. Indiana Univ. Press, Bloomington, Indiana). The invasive cane toad (*Rhinella marinus*) is expected to reach the site within the next 2–3 years, and *V. mitchelli* suffer severe population-level declines due to lethal toxic ingestion of cane toads (Doody et al. 2009. Anim. Conserv. 12:46–53). As such, assuming my observation reflected predation, the frequency of *V. mitchelli* in the diet of the Little Eagles may drop when toads arrive, possibly resulting in a dietary shift for those eagles that hunt along water-courses. Both species are common along watercourses, and both are relatively common at the site (pers. obs.).

J. SEAN DOODY, Department of Ecology and Evolutionary Biology, 569 Dabney Hall, University of Tennessee, Knoxville, Tennessee 37996-1610, USA; e-mail: jseandoody@gmail.com.

***XANTUSIA SIERRAE* (Sierra Night Lizard). REPRODUCTION.** *Xantusia sierrae* is restricted to a few localities along the

western foothills of the Greenhorn Mountains from near Woody south to the Kern River, Kern Co., California, USA (Leavitt et al. 2007. Mol. Ecol. 16:4455–4481). The purpose of this note is to provide information on the timing of the reproductive cycle of *X. sierrae*.

Twelve *X. sierrae* consisting of four males (mean SVL = 44.0 ± 1.2 SD, range = 43–45 mm) and eight females (mean SVL = 46.0 ± 3.5 SD, range = 40–49 mm) collected at Granite Station (35.61389°N, 118.85889°W; 513 m elev.), Kern Co., California were examined from the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA: LACM 76131, 76133, 76134, 76137, 76138 (collected April 1971); LACM 134549, 134551, 134552, 134554, 134562–134564 (collected June 1982).

Ovaries and testes were histologically examined except for enlarged follicles (> 4 mm), which were counted, and two females (LACM 76137 and 76138), which contained very small ovaries that were not reproductively active. Tissues were embedded in paraffin, histological sections, were cut at 5 µm, and stained with hematoxylin followed by eosin counterstain. Histology slides were deposited in LACM.

Spermiogenesis in which the seminiferous tubules are lined by sperm or clusters of metamorphosing spermatids was observed. The two smallest spermiogenic males of *X. sierrae* both measured 43 mm SVL (LACM 134562, 134564), slightly larger than the average size of maturity in male *X. vigilis* (38–39 mm; Miller 1951. Copeia 1951:114–120).

Five females with quiescent ovaries (no yolk deposition), and three females with enlarged follicles (> 4 mm) were observed. Because the follicles of these three females from late June had not ovulated, parturition likely would have been completed in early fall. Mean litter size (N = 3) was 1.7 ± 0.58 SD, range = 1–2). The two smallest reproductively active females (follicles > 4 mm) both measured 48 mm SVL (LACM 134551, 134554), larger than the average size of maturity in female *X. vigilis* (38–39 mm; Miller, *op. cit.*). Whether two smaller females (SVL 40 mm and 42 mm) were mature is questionable as females of mature size of the congeners *X. riversiana* (Goldberg and Bezy 1974. Herpetologica 30:350–360) and *X. henshawi* (Goldberg 2013. Son. Herpetol. 26:9–11) do not reproduce every year.

Xantusia sierrae is a spring breeder with one to two young produced, likely in early fall. *Xantusia sierrae* follows a reproductive cycle in which timing of events and litter size are similar to the closely related *X. vigilis* (Miller 1948. Univ. California Publ. Zool. 47:197–213; Zweifel and Lowe 1966. Am. Mus. Novitat. 2247:1–57) as well as to *X. henshawi* (Lee 1975. Trans. San Diego Nat. Hist. 17:259–278; Goldberg, *op. cit.*).

We thank G. Pauly (LACM) for permission to examine *X. sierrae*.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **ROBERT L. BEZY,** Section of Herpetology, Natural History Museum of Los Angeles County, Los Angeles, California 90007, USA (e-mail: robertbezy@gmail.com).

SQUAMATA — SNAKES

***AGKISTRODON PISCIVORUS* (Cottonmouth). DIET.** *Agkistrodon piscivorus* is known to take a variety of prey, including many species of snakes (Graham et al. 2010. Herpetol. Rev. 41:88–89; Ernst and Ernst 2011. Venomous Reptiles of the United States, Canada, and Northern Mexico, Volume 1. Johns Hopkins Univ. Press, Baltimore, Maryland. 352 pp.). Herein we report a prey item novel for *A. piscivorus*.

FIG. 1. *Agkistrodon piscivorus* scavenging an apparently road-killed *Farancia erytrogramma* in Mississippi, USA.

On 30 April 2013 at 1147 h, one of us (AW) observed an *A. piscivorus* in the process of consuming a female *Farancia erythrogramma* (Rainbow Snake; SVL = 91.2 cm; total length = 104.9 cm; 1070 g) along the edge of a roadside ditch that drains into Flint Creek, Wiggins, Stone Co., Mississippi, USA. The *F. erythrogramma* appeared lifeless and had been a quarter of the way ingested (tail first) when first detected. Upon approach the *A. piscivorus* regurgitated the *F. erythrogramma* and fled upstream. The head of the *F. erythrograma* appeared to have been crushed/flattened and maggots (Order: Diptera) were present on the head and first third of the body. The presence of fly larvae suggests that the *F. erythrogramma* was dead prior to partial ingestion by the *A. piscivorus*, and while it is unknown how the snake may have died, a small blood stain on the adjacent road implies that the *F. erythrogramma* was hit by a car. The frequency and propensity to scavenge and the relative contribution that carrion represents in the diet of *A. piscivorus* is unknown. However, carrion probably plays an important supplementary role, as is the case with a number of other snake species (DeVault and Krochmal 2002. Herpetologica 58:429–436).

JAMES R. LEE, The Nature Conservancy, Camp Shelby Joint Forces Training Center, CSJFTC-ENV, Building 6530, Camp Shelby, Mississippi 39407, USA (e-mail: jlee@tnc.org); **LYNN McCOY**, P.O. Box 1, Hurley, Mississippi 39555, USA (e-mail: wildlifefish@bellsouth.net); **ANNIE WALKER**, 41 Decalb Oneal Road, Perkinston, Mississippi 39573, USA (e-mail: anniewalker514@gmail.com).

***AGKISTRODON PISCIVORUS* (Cottonmouth). DIET and PREY SIZE.** At 1200 h on 9 July 2012, a radio-telemetered *Crotalus horridus* (Timber Rattlesnake) at a field site in Beaufort Co., South Carolina, USA, was found consumed by an *Agkistrodon piscivorus*. The adult female *C. horridus* was implanted on 31 May 2011, at which time it measured 117.0 cm total length and weighed 1012.5 g. The telemetered rattlesnake was previously tracked and visually observed on 26 June 2012 approximately 50

m from the *A. piscivorus* in cane-dominated bottoms at the transition from hardwood forest to saltwater marsh. During the period in which the snake was radio-tracked, no food bulges were observed and the snake's vertebrae were becoming noticeable; this emaciated state likely increased its vulnerability to being depredated or its death upon which it was scavenged.

The *A. piscivorus* was captured and set up overnight in the temperature-controlled treatment room at the Jekyll Island Authority's Georgia Sea Turtle Center on Jekyll Island, Georgia, USA, but was found dead at 0830 h the following morning. A necropsy revealed that the *A. piscivorus* (109.5 cm total length; 1125.6 g excluding the *C. horridus*) was a reproductively-active male in good body condition. A small laceration was noted on the dorsal lower third of the body as well as some tissue damage near the spine and a minor vertebral fracture not compromising the spinal cord, but no puncture wounds or localized tissue necrosis was found. The histopathology report did not provide any further explanation regarding the cause of death for the *A. piscivorus*. The only remains of the *C. horridus* were eleven rattles, caudal scutes, and the transmitter. Therefore, it was determined unlikely that the death was caused or influenced by the *C. horridus*, either through envenomation or digestive impaction. Additionally, due to the advanced digested state of the *C. horridus*, it could not be determined whether the rattlesnake was predated or scavenged.

Agkistrodon piscivorus are dietary generalists feeding on both endo- and ectothermic animals. Further, they exhibit cannibalism (Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex. SSAR, Oxford, Ohio. 614 pp.) and will readily scavenge carcasses (Gloyd and Conant, *op. cit.*; Berna and Gibbons 1991. Herpetol. Rev. 22:130–131; Lilywhite et al. 2008. BioScience 58:947–955). There are at least two records of *A. piscivorus* feeding on rattlesnakes. An *A. piscivorus* kept in captivity at the Toledo Ohio Zoo killed and ate a *Crotalus oreganus* (Pacific Rattlesnake; Gloyd and Conant, *op. cit.*). On another occasion an *A. piscivorus* from South Carolina reportedly regurgitated a *C. horridus* large enough to have acquired seven rattles, but no further explanation on sizes were provided (Kauffeld 1957. Snakes and Snake Hunting. Hanover House, Garden City, New York. 266 pp.). Although rattlesnakes have been documented in their diet, this is the first we know about involving a large reproductive adult *C. horridus* of comparable size in the wild. The total length of the *C. horridus* (taken a year prior to ingestion) exceeded that of the *A. piscivorus* by 7.5 cm.

No current research suggests that *C. horridus* are immune to the venom of *A. piscivorus*. We suspect this predator-prey association may not be a rare occurrence given the overlap in geographic range, habitat use, and activity patterns of these two species. However, given the abundance of other prey items that would present reduced risk, it seems plausible that these predation events are opportunistic and relatively rare in comparison to consumption of small mammals, fish, lizards, and nonvenomous snakes.

JOSEPH E. COLBERT (e-mail: jocolb@uga.edu), **KIMBERLY M. ANDREWS**, and **TERRY M. NORTON**, Jekyll Island Authority, Georgia Sea Turtle Center, 214 Stable Road, Jekyll Island, Georgia 31527, USA.

***AGKISTRODON PISCIVORUS* (Cottonmouth). FIRE MORTALITY.** Periodic fire is an important force maintaining fire-dependent natural communities and associated snake assemblages. Although telemetered snakes have been observed avoiding fire (Withgott and Amlaner 1996. Herpetol. Rev. 27:145–146; Rudolph et al. 1998. Herpetol. Rev. 29:146–148), those inhabiting fire-maintained ecosystems can be vulnerable to fire. For example, searches conducted immediately after North American prairie fires have documented fire-induced snake mortality on multiple occasions (Bigham et al. 1964. Proc. Oklahoma Acad. Sci. 44:47–50; Erwin and Stasiak 1979. Am. Midl. Nat. 101:247–249; Siegel 1986. Biol. Conserv. 35:333–346; Frese 2003. Herpetol. Rev. 34:159–160). Numbers of snakes killed by fire, however, are typically low. Here, I provide observations of *Agkistrodon piscivorus* mortality immediately following a prescribed fire. Insofar as I am aware, this is only the second report of *A. piscivorus* killed by fire (Komarek 1969. Proc. Tall Timbers Fire Ecology Conference 9:161–207) and the first at a communal hibernaculum.

My observations occurred in the Shawnee National Forest, Union Co., Illinois, USA. At this site, large numbers of *A. piscivorus* over-winter in a rocky, west-facing forested hillside dominated by oaks (*Quercus* spp.), hickories (*Carya* spp.), Sweetgum (*Liquidambar styraciflua*), and Tuliptree (*Liriodendron tulipifera*), and summer in an adjacent Buttonbush (*Cephalanthus occidentalis*)-Spadderdock (*Nuphar advena*) wetland. On 26 March 2014, U.S. Forest Service personnel burned approximately 700 ha of forest including the hillside hibernaculum to reduce prevalence of understory mesophytic tree species (Scott Crist, USFS, pers. comm. 28 March 2014). The fire was lit by personnel on the ground and from the air by dropping incendiary devices from a helicopter. On the day of the burn, maximum air temperature was 10°C, the sky was clear, and the wind blew from the SSE at 14.5–18.5 KPH (www.wunderground.com; weather station ca. 14 km from study area). I searched different portions of the burned hillside hibernaculum for snakes on 27 March 2014 (1030–1400 h) and 30 March 2014 (1130–1530 h). I found nine (2 alive, 7 dead) adult *A. piscivorus* on 27 March and four adults (3 alive, 1 dead) on 30 March. Four of the dead snakes were clearly killed by the fire; they were charred and stiff, and died in contorted positions (Fig. 1). Two of the other dead individuals were burned and stiff but not contorted and two, unburned and adjacent to burned leaf litter, may have been killed by the heat of the fire.

At this hibernaculum, *A. piscivorus* typically emerge from dormancy during the latter half of March (pers. obs.) potentially rendering large numbers of snakes vulnerable to fire at this time. The relatively low number of *A. piscivorus* killed by the 26 March 2014 fire was likely due to delayed emergence following a record

FIG. 1. *Agkistrodon piscivorus* killed during a prescribed fire on 26 March 2014 in the Shawnee National Forest, Union Co., Illinois, USA.

cold winter. To prevent mass mortality of *A. piscivorus* at this and other hibernacula, it is recommended that prescribed fires that include dens be conducted during winter months or after snakes have dispersed to summer habitat.

JOHN G. PALIS, Palis Environmental Consulting, P.O. Box 387, Jonesboro, Illinois 62952, USA (e-mail: jpalis@yahoo.com).

***ATRACTUS SNETHLAGEAE* (Ground Snake). DIET.** *Atractus snethlageae* is a relatively large member of the genus *Atractus* and is found throughout much of the Amazon Basin up to elevations of 1800 m (Schargel et al. 2013. Zootaxa 3721:455–474). Earthworm chetae and insect remains have been found in the stomachs of *A. snethlageae* in central Amazonia, Brazil (Martins and Oliveira 1998. Herpetol. Nat. Hist. 6:78–150). On 11 July 2010 at approximately 1600 h an adult male *A. snethlageae* (SVL = 328 mm, tail length = 66 mm, 19.51g) was collected in lower montane secondary forest 1500 m elev. at Wildsumaco Wildlife Sanctuary in eastern Napo Province, Ecuador (0.67557°S, 77.60116°W; datum WGS84) that had consumed an earthworm (Fig. 1). The snake appeared to have recently swallowed the earthworm when collected because the worm's posterior end was visible in the snake's throat. The snake's head was 14.6 mm long and 8.2 mm wide. The worm was swallowed head first and measured 157 mm in length and 11.1 mm wide and weighed 5.89 g. The mass ratio for this prey item was 0.302. The snake (QCAZ 10639) and stomach contents are deposited in the Museo de Zoologia of the Pontificia Universidad Catolica del Ecuador in Quito.

We are especially grateful to our Ecuadorian collaborators Santiago Ron and Omar Torres for aid during all aspects of the work. James Olson, Bonnie Olson, and Jonas Nilsson generously allowed access to the Wildsumaco property.

FIG. 1. Ventral view of an adult male *Atractus snethlageae* (QCAZ 10639) with an earthworm that it swallowed prior to capture.

JEFFREY D. CAMPER, Department of Biology, Francis Marion University, Florence, South Carolina 29506, USA (e-mail: JCamper@fmarion.edu); **DAVID J. ZART**, 10580 Majesty Lane, Concord TWP, Ohio, USA.

***BOTHROPS ASPER* (Terciopelo). PARTHENOGENETIC REPRODUCTION.** On 26 November 2012 a female *Bothrops asper* (SVL = 125 cm; tail length = 14.5 cm; 956 g) housed on exhibit in the Dallas Zoo's reptile building gave birth to 11 unfertilized ova and one full term dead neonate. This seven-year old adult female was born at the Dallas Zoo and had never been housed with a male. Although the neonate was stillborn, the body was fully formed thus indicating fertilization. We believe this is the first example of parthenogenesis reported for this species. The male neonate (SVL = 120 mm; tail length = 40 mm; 6.5 g) was deposited at the Amphibian and Reptile Diversity Research Center at the University of Texas at Arlington (UTA R 61066). Because the mother is still living, a recent shed was deposited as well to confirm there were no other DNA contribution except from the female.

MATTHEW S. VAUGHAN (e-mail: matthew.vaughan@dallaszoo.com) and **RYAN A. STEELE** (e-mail: ryan.steele@dallaszoo.com), Department of Herpetology, Dallas Zoo Management Inc, 650 S R L Thornton, Dallas, Texas 75203, USA.

***BOTHROPS MOOJENI* (Brazilian Lancehead). DIET.** *Bothrops moojeni* is a pitviper that is found most often in open areas associated with riparian forests (Araújo and Martins 2006. Herpetol. J. 16:297–303). The species has a generalist diet (Leloup 1984. Acta Zool. Pathol. Antv. 78:177–198) including birds (França et al. 2008. Copeia 2008:23–38); however, to our knowledge there are no studies reporting which bird species are predated by *B. moojeni*. Analyzing stomach contents of pitvipers collected in the municipality of Lucas do Rio Verde, Mato Grosso, Brazil (12.79694°N, 56.01055°E, datum WGS84; Tavares et al. 2012. Herpetol. Notes 5:543–545), we found in the stomach of a female *B. moojeni* (SVL = 104 cm, tail length = 15.5 cm, 402.4 g) a small *Sporophila nigricollis* (body length = 8.2 cm, 27.36 g), a migratory seed-eating bird with diurnal activity (Andrade et al. 2011. Rev. Bras. Ornitol. 19:63–73).We acknowledge Josué da Silva Ribeiro Nunes for the identification of the bird.

***CARPHOPHIS AMOENUS* (Eastern Worm Snake). ASSOCIATION WITH ANTS.** *Carphophis amoenus* is a small-bodied, largely fossorial colubrid (Barbour et al. 1969. Ecology 50:470–476). Species with a similar ecology (*C. vermis*, *Diadophis punctatus*, *Virginia valeriae*) have been documented utilizing dormant formicid ant nests as hibernacula (Pisani 2009. Trans. Kansas Acad. Sci. 112:113–118). Herein, I present information suggesting a more extensive relationship between formicid ants and *C. amoenus*.

I searched for *C. amoenus* within naturally occurring coarse woody debris (CWD) at two sites (located in Anne Arundel Co., Maryland and Fairfax Co., Virginia, USA) during May, June, and July of 2012 and 2013. Ant colonies were more commonly seen in CWD where *C. amoenus* were present than in CWD where *C. amoenus* were absent (49.5% [47/95] and 26.4% [23/87], respectively; $\chi^2 = 10.2$, $p = 0.001$). There was no association between snakes and termites ($\chi^2 = 3.18$, $p = 0.07$) and significantly fewer snakes were observed in CWD with earthworms ($\chi^2 = 12.3$, $p < 0.001$). Snakes were in close association with ants during all study months. However, it is unknown whether this association reflects an overlap in microhabitat preferences or a commensal

relationship. I observed no aggressive behavior of ants towards the snakes, even when ant colonies were active. Furthermore, snakes regularly used ant tunnels as escape routes in areas where the soil was compacted. *Carphophis amoenus* are poor burrowers (Clark 1970. Univ. Kansas Publ. Mus. Nat. Hist. 19:85–194) and thus may rely on ant tunnels to penetrate compacted soils.

I thank Todd A. Tupper for his helpful comments on the draft of this note.

KARA S. JONES, George Mason University, Department of Environmental Science and Policy, 4400 University Drive, Fairfax, Virginia 22030, USA; e-mail: kcurtain@gmu.edu.

***CHARINA BOTTAE* (Rubber Boa). DIET.** *Charina bottae* is a short boa that averages around 0.5 m long and is known to consume small mammals, lizards, birds, and small eggs (Rodriguez-Robles et al. 1999. J. Zool. 248:49–58). On 6 August 2012, at 1300 h, I found a *C. bottae* in the process of killing and consuming a chipmunk (Fig. 1) around basalt columns on bluffs overlooking Lake Tahoe, above CA Hwy 89 running between Truckee and Tahoe City, California, USA (39.166573°N, 120.166026°W, datum WGS84; elev. 2001 m). The chipmunk was identified as *Tamias quadrimaculatus* (Long-Eared Chipmunk) by its white postauricular patches and malar stripe that connects with the postauricular patches (Clawson et al. 1994. *In* Lackey and Koopman [eds.], Mammalian Species, pp. 1–6. American Soc. Mammalogists, no. 469, Auburn, Alabama). The snake killed the chipmunk by constriction and then fully consumed it. To the best of my knowledge, this is the first record of *C. bottae* preying upon *T. quadrimaculatus*. I thank Kerry Foresman for help with chipmunk identification. Also, I thank Chris Feldman and Art Woods for their help in preparation of this note.

FIG. 1. *Charina bottae* constricting a *Tamias quadrimaculatus* (Long-Eared Chipmunk) near Lake Tahoe, California.

NEIL MOORE, 113 Miller Hall, Rm. 459A, Missoula, Montana 59801, USA; e-mail: neil.moore@umontana.edu.

***COLUBER CONSTRICTOR PRIAPUS* (Southern Black Racer). DIET.** *Coluber constrictor* is known to have a varied diet, including anurans. It has been reported to feed on several frogs of the genus *Hyla*, including *H. chrysoscelis*, *H. cinerea*, *H. femoralis*, and *H. versicolor* (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Institution, Washington DC. 668 pp.). On 21 March 2014, we observed an adult female *C. constrictor* (SVL = 113.1 cm; total length = 133 cm; 480 g) in the process of swallowing an adult male *H. gratiosa* (Barking Treefrog; Fig. 1), near an ephemeral pond on the Camp Shelby Joint Forces Training Center, De Soto National Forest, Perry Co., Mississippi, USA. The *C. constrictor* had the *H. gratiosa* about half way ingested when JRL caught it by hand, and at which point the frog was released. Known predators of *H. gratiosa* include dragonfly naiads, Mole Salamanders, and snakes (*Nerodia fasciata, Heterodon simus,* and *Agkistrodon piscivorus*) (summarized by Mitchell 2005. *In* M. Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 455–456. Univ. California Press, Berkeley).

FIG. 1. Adult female *Coluber constrictor* ingesting an adult male *Hyla gratiosa* in Perry Co., Mississippi, USA.

***COLUBER* (=*MASTICOPHIS*) *FLAGELLUM* (Coachwhip). REPRODUCTION.** *Coluber flagellum* is common in the southeastern United States and often inhabits beach dune systems and interdune swales in coastal areas and barrier islands. Mating generally occurs in spring and females lay clutches of 2–16 eggs

FIG. 1. *Caretta caretta* hatchling and *Coluber flagellum* embryo upon excavation.

in late summer (Force 1930. Copeia 1930:25–39; Goldberg 2002. Texas J. Sci. 54:143–150). The literature suggests that *C. flagellum* nesting in the southeastern USA generally occurs in decomposing vegetation or logs (Guidry 1953. Herpetologica 9:49–56). There are no descriptions of the reproductive habits of *C. flagellum* on barrier islands.

On 5 August 2013, during excavation of a *Caretta caretta* (Loggerhead Sea Turtle) nest on the southern end of Jekyll Island, Georgia, USA (31.0153°N, 81.4231°W; datum WGS84), three *C. flagellum* eggs were found buried in the nest chamber. Eggs had been laid as a slightly lower depth than the recently hatched *C. caretta* eggs. The eggs were oblong, granular in texture, and a size typical of *C. flagellum* and *C. constrictor* (North American Racer) eggs. Upon opening the first oblong egg, a developing *C. flagellum* embryo with a large umbilicus still attached was found. The embryo was almost fully developed and responsive but still too early to survive outside of the egg given the incubation time noted for *M. flagellum* (Behler and King 1979. The Audubon Society Field Guide to North American Reptiles and Amphibians. Alfred A. Knopf, Inc., New York. 744 pp.). The remaining two eggs found were incubated and hatched on 15 August 2013. This is the first documentation of *C. flagellum* reproduction in beach dunes and in a sea turtle nest.

K. NICOLE WHITE (e-mail: knwhite21@gmail.com), **KIMBERLY M. ANDREWS,** University of Georgia Savannah River Ecology Lab, Aiken, South Carolina 29802, USA, and Georgia Sea Turtle Center, Jekyll Island, Georgia 31527, USA; **ETHAN B. CHAPMAN,** Francis W. Parker School, Chicago, Illinois 66014, USA.

***CROTALUS ATROX* (Western Diamond-backed Rattlesnake). DIET.** Mammals are the prey most routinely selected by *Crotalus atrox* in Texas, but birds are also infrequently consumed (Beavers 1976. Southwest. Nat. 20:503–515). In other parts of the range, birds are similarly uncommon in the diet (Pisani and Stephenson 1991. Trans. Kansas Acad. Sci. 94:137–141). However, earlier studies have focused on the diet of adult *C. atrox* and species-specific identification details of predation upon birds in previous studies are lacking.

On 21 April 2014, at 1946 h, a mixed group of *Spiza americana* (Dickcissel) and *Chondestes grammacus* (Lark Sparrow) were observed on the entrance road to Laguna Atascosa National Wildlife Refuge (26.173833°N, 97.356222°W, datum NAD83; elev. 6 m), Cameron Co., Texas, USA. A juvenile *C. atrox* emerged shortly thereafter from the adjacent grassland, then envenomed and held a *Ch. grammacus* from the flock. The *Ch. grammacus* began convulsing and was ingested by the snake (Fig. 1). The influence of *C. atrox* predation on *Ch. grammacus* is unclear; however, the similarity of habitat association and the tendency of sparrows to forage on the ground suggests that the frequency of predation could be persistent.

FIG. 1. Juvenile *Crotalus atrox* consuming *Chondestes grammacus* (Lark Sparrow) near Laguna Atascosa National Wildlife Refuge, Cameron Co., Texas, USA.

CODY L. BARNES, Department of Zoology, Oklahoma State University, Stillwater, Oklahoma 74074, USA; e-mail: cody.l.barnes@okstate.edu.

***CROTALUS HORRIDUS* (Timber Rattlesnake). COLORATION.** The ground color of *Crotalus horridus* in Minnesota has been described as yellow, tan, brown, reddish brown, "or, rarely, gray" (Oldfield and Moriarty 1994. Amphibians and Reptiles Native to Minnesota. Univ. Minnesota Press, Minneapolis. 240 pp.) and in Wisconsin as yellow, rust-orange, brown, or "very rarely gray" (Vogt 1981. Natural History of Amphibians and Reptiles of Wisconsin. Milwaukee Public Museum, Milwaukee. 205 pp.). Multiple photographs of typical snakes from this region were provided by Keyler (2004. *In* Kaufman [ed.], North: Stories and Photographs, pp. 67–87. Crotalus Publishing, Plymouth, Minnesota). While monitoring den complexes at two sites in Winona Co. and Houston Co. in southeastern Minnesota, USA, and handling nuisance rattlesnakes, I collected data on gray individuals.

Gray *C. horridus* have a gray to light gray ground color and black eyes (Fig. 1), a pattern that perhaps represents retention of newborn coloration. This pattern is similar to that described for southern morph *C. horridus* in the southern USA, where gray snakes are apparently more common, but descriptions from that region emphasize the presence of an orange to reddish brown middorsal stripe (e.g., Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville. 421 pp.). A middorsal stripe may be present in Minnesota snakes, but I have not yet observed it in a gray snake. At the Winona Co. site, 2 of 52 nuisance snakes PIT-tagged during 2006–2012 were gray. An upper bound to the proportion of gray snakes is provided by the numbers observed at two den openings (one of eight and one of nine). At the Winona Co. site, four gray individuals observed in 2012 included two males and a female with young. At the Houston Co. site, no gray snakes were observed during 2006–2012. If populations of *C. horridus* in Minnesota have declined and become more isolated from one another, it is not unexpected that some genetic traits have become more abundant in some locations.

I thank the other rattlesnake responders of Winona County and the students who assisted me in the field or in the laboratory.

FIG. 1. A gray *Crotalus horridus* from Winona Co., Minnesota, USA.

PHILIP A. COCHRAN, Biology Department, Saint Mary's University of Minnesota, 700 Terrace Heights, Winona, Minnesota 55987, USA; e-mail: pcochran@smumn.edu.

***CROTALUS HORRIDUS* (Timber Rattlesnake). DIEL ACTIVITY.** *Crotalus horridus* in southeastern Minnesota hibernate in dens associated with rock outcrops high on south- or southwest-facing slopes of bluffs (Cochran 2008. *In* Hayes et al. [eds.], The Biology of Rattlesnakes, pp. 441–446. Loma Linda Univ. Press, Loma Linda, California). Most often the hibernacula are found in or near bluff prairies (locally referred to as "goat prairies"). Whereas males and nongravid females disperse during the summer, gravid females remain at dens or in nearby rocky habitat. To monitor daily and seasonal use of this habitat, in 2007 we placed two remote cameras beneath overhanging rock ledges on bluffs in Houston Co. (22 May – 5 October) and Winona Co. (27 July – 6 October). At each location, the camera was set beneath one end of an overhanging ledge and pointed toward the opposite end. At one ledge in Houston Co., substrate temperatures were recorded hourly (HOBO) beneath the overhanging ledge and on the exposed ground surface approximately two meters from the ledge.

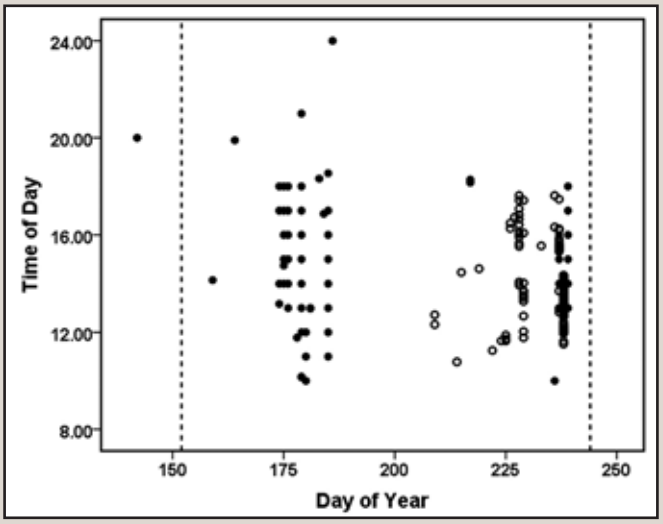

FIG. 1. Times when photographs of *C. horridus* were taken in Houston Co, Minnesota, USA (solid dots) and in Winona Co, Minnesota, USA (open circles). Vertical reference lines indicate June 1 and September 1.

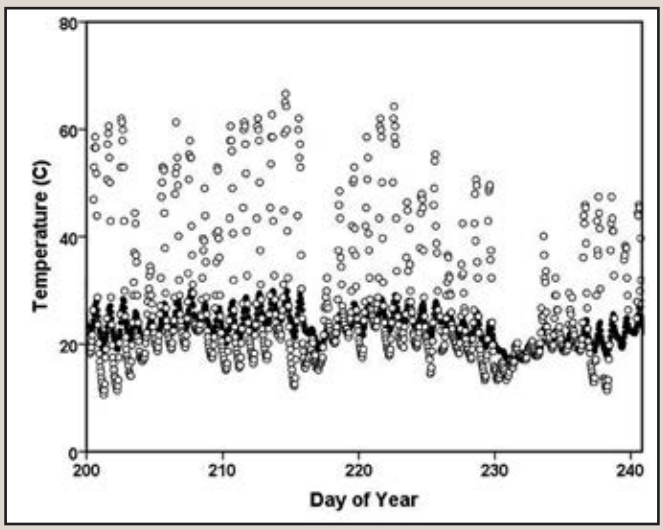

FIG. 2. Ground surface temperature (°C) beneath the Houston Co. ledge (solid dots) and in the open approximately 2 m from the ledge (open circles).

The camera in Houston Co. captured 57 images of *C. horridus*; 103 images were captured in Winona Co. Although distributions of times at which photographs were taken were significantly different between the two sites, *C. horridus* photographs were obtained primarily during the hours 1000 h–1800 h at both locations (Fig. 1). Observed frequencies of photographs in two-hour blocks during the daylight period (0600–2000 h) were significantly different from those that would be expected if photographs were equally likely in any time block (Houston Co.: $\chi^2 = 27.123$, df = 6, $P < 0.001$; Winona Co.: $\chi^2 = 141.906$, df = 6, $P < 0.001$).

Ground surface temperature beneath the Houston Co. ledge had a narrower range of fluctuation than the exposed ground surface outside the ledge (Fig. 2). Temperature beneath the ledge ranged from approximately 20°C at night to approximately 30°C during the day. Temperature of the exposed ground surface outside the ledge often fell below 20°C at night and sometimes climbed above 50°C during the day. Data plotted for a typical day (19 July) reveal that exposed ground surface temperature was lower than the temperature beneath the ledge until sometime between 1000 h and 1100 h, peaked at approximately 1600 h, and dropped below the temperature beneath the ledge at approximately 2000 h (Fig. 3).

Crotalus horridus apparently use overhanging rock ledges as thermal refuges during the hottest part of the day. The times when photographs were obtained correspond well with the period in the day when ground surface temperatures in the open exceed those beneath the ledge (Fig. 3). Cochran and Schmitt (2009. Bull. Chicago Herpetol. Soc. 44:161–165) provided an hourly sequence of photographs at the Houston Co. site depicting how a *C. horridus* kept its body tightly coiled within the shade of the overhanging ledge during a bright sunny afternoon and then moved underground at sundown. It may be especially important for reproductive females to be able to thermoregulate precisely and thereby keep the temperature of their developing offspring within appropriate bounds.

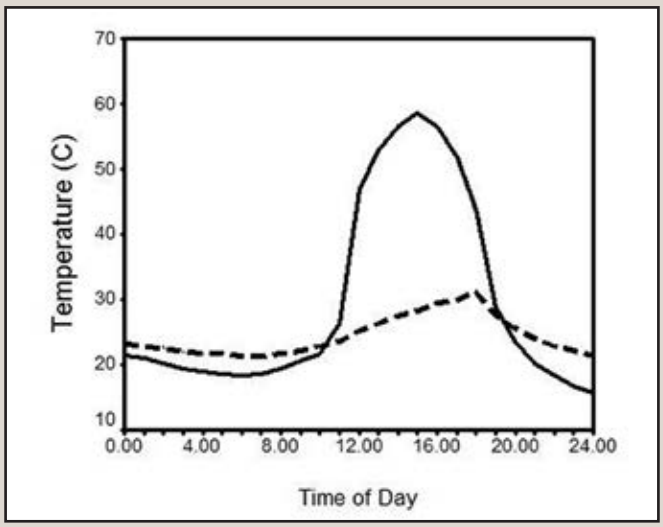

FIG. 3. Ground surface temperature (°C) beneath the Houston Co. ledge (dashed line) and in the open approximately 2 m from the ledge (solid line) on 19 July 2007.

We thank the Chicago Herpetological Society for a grant to purchase a remote camera and Chris Kendall for access to one of the study sites. Stephen Schmitt is grateful to Saint Mary's University of Minnesota for its support of undergraduate research.

PHILIP A. COCHRAN (e-mail: pcochran@smumn.edu), and **STEPHEN J. SCHMITT**, Biology Department, Saint Mary's University of Minnesota, 700 Terrace Heights, Winona, Minnesota 55987, USA.

***CROTALUS HORRIDUS* (Timber Rattlesnake). HABITAT USE.** On 6 October 2013, a *Crotalus horridus* was observed under an automated corn feeder hung above a small clearing next to an adjacent forest patch on private property in Columbia Co., Lulu, Florida, USA. The snake was present for at least 5 h, noted from timestamps on images taken on a game camera. At 0711 h, it was still dark, and the snake was coiled in the center of the clearing, which was shaded until approximately 1030 h. As the day progressed, photos show the snake continually shifted its position within the plot to stay just out of direct sunlight, remaining at the interface of sun and shade.

At 1243 h, the snake was in the shade next to the only log within the confines of the clearing. It is assumed to have been foraging, as it was in a compact coil position next to the log with its head facing perpendicular to it (Reinert et al. 1984. Copeia 1984[4]:976–981). *Odocoileus virginianus* (White-tailed Deer) were observed multiple times from early morning to early afternoon feeding on corn within a few meters of the snake (Fig. 1). In addition to this observation, a *C. horridus* was noticed in the same spot five days earlier, and *C. horridus* have been witnessed on this feeder plot on several occasions, as well as at a different feeder in a forested area ca. 300 m away. Whether the same individuals are being repeatedly seen is unknown.

C. horridus often spend long periods of time at ambush sites (Clark 2006. Copeia 2006[2]:181–187) and may have to make tradeoffs between selecting sites for foraging and thermoregulation. Due to the food supply for small mammals, which make up a substantial portion of the diet for *C. horridus* (Clark 2002. J. Herpetol. 36:494–499), as well as the lack of canopy cover, clearings with feeders or planted food plots may offer thermoregulatory benefits for snakes while simultaneously attracting prey (Hampton et al. 2010. Am. Midl. Nat. 163:44–53). Because the clearing in this observation is surrounded by a fence to deter feral hogs, which are known predators of pitvipers, it may also afford added protection from predation.

FIG. 1. *Crotalus horridus* (Timber Rattlesnake) in an ambush position near an *Odocoileus virginianus* (White-tailed Deer) at an automated corn feeder in Columbia Co., Florida, USA.

I thank Ron Benke for assistance. David Tetzlaff and Michael Ravesi provided thoughtful suggestions to the manuscript.

SASHA J. TETZLAFF, Department of Biology, Indiana University-Purdue University Fort Wayne, 2101 E. Coliseum Boulevard, Fort Wayne, Indiana 46805, USA (e-mail: tetzsj01@ipfw.edu).

***DIADOPHIS PUNCTATUS* (Ring-necked Snake). DIET.** *Diadophis punctatus* shows considerable dietary diversity among and within populations. This includes heavy reliance on prey items as diverse as earthworms and other invertebrates, amphibians, or squamate reptiles, which challenges the commonly held assumption that these are earthworm specialists (reviewed by Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, Washington, DC. 680 pp.). O'Donnell et al. (2007. Toxicon 50:810–815) reviewed the chemistry of oral secretions and instances of apparent envenomation of prey items by some, but not all, populations of *D. punctatus* across its range (see also chemical analyses by Hill and Mitchell 2000. Toxicon 38:1663–1687). Mitchell (1994. The Reptiles of Virginia, Smithsonian Inst. Press, Washington, DC. 352 pp.) stated that prey items in Virginia, USA, were killed by constriction—a behavior not reported by other authors (e.g., Henderson 1970. Herpetologica 26:520–526; but see also references cited therein). O'Donnell et al. (*op. cit.*) and Ernst and Ernst (*op. cit.*) presented direct evidence of lethal envenomation by oral secretions from *D. punctatus* on several taxa. We (JRM, unpubl. data) once observed a *Plethodon serratus* become motionless and evidently dead (no heartbeat visible) within seconds of a predatory bite by a sympatric *D. punctatus* from LeFlore Co., Oklahoma, USA. There are conflicting reports of human envenomations (e.g., Myers 1965. Bull. Florida State Mus. Nat. Hist. 10:43–90; Henderson, *op. cit.*; Shaw and Campbell 1974. Snakes of the American West. Alfred A. Knopf, New York, New York. 330 pp.).

An adult *D. punctatus* (UCSB 25830; SVL = 148 mm; preserved mass = 6.25 g) found on More Mesa, Goleta, Santa Barbara Co., California, USA, on 11 April 1987 contained a visible abdominal bulge consistent with a large prey item. After capture, the snake regurgitated a subadult *Elgaria multicarinata* (UCSB 25831; minimum SVL = 52 mm; preserved/dry mass = 1.5 g; keeling on dorsal scales evident). This is the first record of *Elgaria* in the diet of *Diadophis* of which we are aware (Ernst and Ernst, *op. cit.*).

FIG. 1. *Diadophis punctatus* from Santa Barbara Co., California, with subadult *Elgaria multicarinata* regurgitated soon after capture.

The lizard prey was sufficiently digested, and missing part of the tail, such that calculation of prey/predator mass ratio can only be approximated (0.24, post preservation). Nevertheless, it is a large prey item for such a diminutive snake (Fig. 1) and *Elgaria* spp. are capable of formidable antipredator bites. We have observed (JRM, unpubl. data) a variety of obligate constricting snakes (e.g., *Lampropeltis* spp.) to become incapacitated, or badly injured, by the antipredatory bite-and-hold response of *E. multicarinata*; furthermore, these observations of *Lampropeltis* spp. included snakes proportionally much larger than is this *D. punctatus* with respect to the intended prey items. All points considered together, we conclude that *D. punctatus* in central California are capable of subduing robust squamate prey species, supporting the suggestion by O'Donnell et al. (*op. cit.*) that venom evolved in this species to facilitate subjugation of larger prey items.

The variety of prey items and feeding behavior and contradictory reports of effects of bites delivered to humans by *Diadophis* suggest that considerable geographic variation in the diet, behavior, and perhaps oral secretions of this snake exists. We emphasize the observation by O'Donnell et al. (*op. cit.*) that snakes referable to *D. p. edwardsii* lack the enlarged rear fangs that are present in the other putative subspecies. We suggest that carefully documented feeding trials involving snakes from various regions and presented with a variety of types of potential prey would reveal a surprising diversity of results perhaps consistent with the complex evolutionary history of these snakes (Fontanella et al. 2007. Mol. Phylog. Evol. 46:1049–1070; Fontanella and Siddall 2010. Zool. J. Linn. Soc. 158:629–640).

We thank S. S. Sweet and M. Beas-Moix for access to the UCSB herpetological collections, H. W. Greene for encouraging us to present our observations, C. D. Anthony for field assistance, and C. R. Feldman and J. D. Willson for useful comments.

JOSEPH R. MENDELSON III, Zoo Atlanta, 800 Cherokee Ave SE, Atlanta, Georgia 30312, USA (e-mail: jmendelson@zooatlanta.org); **ANDREA J. ADAMS,** Department of Ecology, Evolution, and Marine Biology, University of California, Santa Barbara, California 93106, USA.

DIADOPHIS PUNCTATUS **(Ring-necked Snake). DIET.** *Diadophis punctatus* is a fossorial species that ranges across much of the United States into southeastern Canada (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, Washington, DC. 668 pp.). On 3 June 2011, I found a dead *D. punctatus* in a recently mowed yard at 5823 Spanish Oaks Lane, Naples, Florida, USA (26.265215°N, 81.724880°W; datum WGS84). The *D. punctatus* was apparently hit by a mower and upon discovery I noticed a prey item, a *Ramphotyphlops braminus* (Brahminy Blindsnake), an established exotic species in Florida. Given the condition of the *D. punctatus*, it was likely killed the same day it was found. The lack of significant digestion of the *R. braminus* suggests it was recently consumed (Fig. 1).

FIG. 1. A *Diadophis punctatus* (Ring-necked Snake) that had consumed a *Ramphotyphlops braminus* (Brahminy Blindsnake), discovered after being hit by a lawn mower in Naples, Florida, USA.

Diadophis punctatus primarily feeds on small vertebrates, including other native snake species and conspecifics (Ernst and Ernst, *op. cit.*). While other fossorial snake species have been documented to consume *R. braminus*, such as *Stilosoma extenuatum* (Short-tailed Snake; Godley et al. 2008. Herpetol. Rev. 39:473–474) and *Micrurus fulvius* (Harlequin Coralsnake; Krysko et al. 2010. Herpetol. Rev. 41:501–502), this observation represents the first recorded occurrence of *D. punctatus* consuming a *R. braminus*.

I thank Kenneth Krysko and Kevin Enge for assistance.

SASHA J. TETZLAFF, Department of Biology, Indiana University-Purdue University Fort Wayne, 2101 E. Coliseum Boulevard, Fort Wayne, Indiana 46805, USA; e-mail: tetzsj01@ipfw.edu.

EPICRATES CRASSUS **(Eastern Rainbow Boa). DIET.** *Epicrates crassus* occurs in open grassland habitats in Bolivia, central Brazil, Paraguay, and northern Argentina (Passos and Fernandes 2008. Herpetol. Monogr. 22:1–30). In Paraguay most modern records are from the Cerrado zone and it is classed as vulnerable at the national level (Motte et al. 2011. Cuad. Herpetol. 23:5–18). It is considered to be the most terrestrial member of the genus and feeds mainly on small mammals, and occasionally birds (Pizzatto et al. 2009. Amphibia-Reptilia 30:533–544). At ca. 2100 h on 3 March 2014, a mature female *E. crassus* (estimated SVL = 972 mm) was found dead, apparently deliberately decapitated, on a dirt road ca. 8 km from Santa Rosa del Aguaray, Depto. San Pedro, Paraguay (23.8363°N, 56.3899°W; datum WGS84). The surrounding habitat consisted of wet grassland with nearby eucalyptus plantations. The snake had ingested an adult female *Cavia aperea* (Pampas Cavy; Mammalia: Caviidae; alcohol specimen CZPLT-M 438) with greatest length of skull 23 mm. *Cavia aperea* is a new prey species for *E. crassus* and with mean head–body length of 274 mm (Asher et al. 2004. J. Mammal. 85:788–796), and mean body mass of 523.6 g (Künzl and Sachser 1999. Horm. Behav. 35:28–37), is larger than other prey items previously reported (Pizzatto et al. 2009, *op. cit.*). The *Epicrates* specimen is deposited at the Para La Tierra Colección Científica housed at Reserva Natural Laguna Blanca, Departamento San Pedro, specimen number CZPLT-H 697.

KARINA ATKINSON (e-mail: karina@paralatierra.org), and **REBECCA SMITH,** Para La Tierra, Laguna Blanca, San Pedro Department Paraguay, Paraguay; **PAUL SMITH**, FAUNA Paraguay, Encarnación, Paraguay (e-mail: faunaparaguay@gmail.com).

HETERODON PLATIRHINOS **(Eastern Hog-nosed Snake). REPRODUCTION / NEST SITE FIDELITY.** Nest site fidelity is poorly documented in snakes, and in *Heterodon platirhinos* it has been documented only in Ontario, Canada, near the species' northernmost range limit (Cunnington and Cebek 2005. Am. Midl. Nat. 154:474–478). Here, we present evidence of nest site fidelity of *H. platirhinos* from a population in Saratoga Co., New York, USA. As part of a radio-telemetry study, we observed a large female (SVL = 78 cm, mass = 618 g) nesting in a utility right-of-way (characterized by an open canopy and early successional plant

species) at ~1800 h on 17 Jun 2012. After the female finished oviposition, we excavated the nest and located 39 eggs. We re-buried the clutch and it successfully hatched 51 days later on 7 August. At 1500 h on 20 June 2013, the same female was observed nesting within 1 m of her nesting location the previous year. The snake was not interrupted, and was identified via unique tail pattern markings, as she was no longer being radio-tracked. This clutch was depredated by a mammal the following night. To the best of our knowledge, this is the first report of nest site fidelity in *H. platirhinos* outside of Canada, and suggests this behavior might be widespread in the species. Our study also confirms that annual reproduction can occur in wild *H. platirhinos* in New York.

***LAMPROPELTIS MEXICANA* (Mexican Kingsnake). MAXIMUM ELEVATION.** On 8 October 2008, an adult female *Lampropeltis mexicana* (SVL = 65.2 cm, TL = 11 cm; UAA-CV-R263) was found in oak-juniper forest ca. 3.6 km WNW of La Congoja, (22.180879°N, 102.588795°W, datum WGS84; elev. 2603 m), Sierra Fría, Municipality of San José de Gracia, Aguascalientes, México. Previous known vertical distribution for this species is 2000–2440 m elev. (Vázquez-Díaz and Quintero-Díaz 2005. Anfibios y Reptiles de Aguascalientes. CONABIO, CIEMA, México. 318 pp.; Bryson et al. 2007. Mol. Phylogenet. Evol. 43:674–684; Hansen and Bryson. 2009. Herpetol. Rev. 40:114). The specimen is phenotypically similar to populations of *L. m. greeri* from Mesa Montoro. This record extends the distribution ca. 18 km N from previous known locality in the state at Mesa Montoro (Quintero-Díaz et al. 2001. Herpetol. Rev. 32:278) and increases the vertical distribution to 2603 m elev.

We thank Robert Hansen for comments on a previous draft of this note.

***LEPTODRYMUS PULCHERRIMUS* (Striped Lowland Snake). COLORATION.** Blue coloration is found across many groups of organisms and has a variety of utilities such as signaling or crypsis (Bagnara et al. 2007. Pigment Cell Res. 20:14–26; Umbers 2013. J. Zool. 289:229–242). Sometimes, blue coloration can result from a failure to synthesize yellow pigments in typically green species (Bechtel 1978. J. Herpetol. 12:521–532). *Leptodrymus pulcherrimus* is a colubrid snake endemic to the Pacific versant of middle Central America, ranging from Guatemala to Costa Rica. This species typically displays bright green head coloration (green is sometimes seen on the tail also), with a pale dorsal stripe and dark dorsolateral stripes. Around midnight on 30 June 2010, a specimen of *L. pulcherrimus* was collected on the Reserva de la Biosfera Isla de Ometepe, Rivas Dept., Nicaragua (11.51024°N, 85.55843°W, datum WGS84; elev. 32 m). This specimen had dark blue coloration in place of the typical green. Abnormal blue coloration has not yet been reported in *L. pulcherrimus*, but bluish color morphs in other typically green species have been reported (e.g., *Coluber constrictor stejnegerianus*, Webb 1960. Trans. Kansas Acad. Sci. 64:289–298; *Leptophis ahaetulla*, M. E. Acevedo, pers. comm.), and in one documented case, reduced pigment levels caused red coloring to be replaced by blue in *Thamnophis proximus* (Bagnara et al. 1978. Amer. Zool. 18:301–312). We do not currently know what is responsible for the blue coloration in *L. pulcherrimus*, but have observed at least five blue *L. pulcherrimus* on Isla de Ometepe without any records or observations of *L. pulcherrimus* with the typical coloration. We believe our observations to be more than individual abnormalities, and likely a characteristic of the population observed. The specimen (MHUL 161) was collected under the scientific permit DGPN/DB-10–2010 issued by MARENA.

FIG. 1. A *Leptodrymus pulcherrimus* (MUHL 161) from Isla de Ometepe, Nicaragua, displaying blue coloration, unreported for the species, but apparently typical for *L. pulcherrimus* from the island.

***LEPTOPHIS AHAETULLA* (Parrot Snake). DIET.** *Leptophis ahaetulla* feeds primarily on anuran amphibians, particularly species in the family Hylidae, but occasionally eats lizards, young birds, and salamanders (Albuquerque et al. 2007. J. Nat. Hist. 41:1237–1243). On 15 October 2013, in Dois Irmãos state park (08.0119°S, 34.9489°W, datum WGS84; elev. 44 m) in the city of Recife, Pernambuco, Brazil, a *L. ahaetulla* (SVL = 958 mm; tail length = 296 mm) was captured that had consumed a *Hypsiboas semilineatus* (Anura: Hylidae). The most common anurans in the diet of *L. ahaetulla* are in the genus *Scinax* (Albuquerque et al., *op. cit.*); this is the first record of predation on *H. semilineatus*. These species exhibit different active schedules; the snake is diurnal and the anurans are nocturnal, indicating that the snake uses active foraging to locate inactive prey. Specimens were deposited in the Herpetological and Paleoherpetological Collection of the Federal Rural University of Pernambuco – UFRPE, Recife, Brazil (*L. ahaetulla* CHPUFRPE-3007; *H.semilineatus* CHPUFRPE-3006).

***LYCODON FUTSINGENSIS* (Fuqing Wolf Snake). DIET.** Although *Lycodon futsingensis* has been described for many decades (Pope 1928. Am. Mus. Novit. 320:1–6), little is known about its biology,

FIG. 1. Adult *Lycodon futsingensis* feeding on a juvenile *Ptyas dhumnades* in Nanling National Wildlife Refuge, Guangdong, China.

including its diet in the wild. Zhang et al. (2011. Chin. J. Zool. 46:128–130) reported that captive *L. futsingensis* fed primarily on lizards, but no observations have confirmed its diet in nature.

At 2130 h on 15 May 2010, an adult *L. futsingensis* was observed swallowing a juvenile *Ptyas dhumnades* in the dry sluiceway in Nanling National Wildlife Refuge, Guangdong, China (Fig. 1). The *P. dhumnades* was alive and struggling as it was swallowed by the *L. futsingensis*. At 2200 h on 21 July 2011, another adult *L. futsingensis* was observed capturing a *Sphenomorphus incognitus* inside a rock crevice along a stream in Liuxihe National Forest, Guangdong, China. The snake was constricting and swallowing the skink, but the snake fled quickly, leaving the dead skink in the crevice.

Our observations on the diet of *L. futsingensis* are consistent with the previous reports that species in the genus *Lycodon* primarily feed on reptiles (Zhang et al., *op. cit.*; Pauwels et al. 2005. Nat. Hist. Bull. Siam. Soc. 53:79–86; Vogel et al. 2009. Trop. Zool. 22:131–182). Additionally, *Ptyas dhumnades* represents a new species of the natural diet of *L. futsingensis*. Based on observations in natural settings and under captivity, we suggest that the diet *L. futsingensis* consists mainly of skinks, geckos, and small snakes, and the species forages primarily at night.

LIANG ZHANG, Guangdong Entomological Institute & South China Institute of Endangered Animals, Guangzhou, Guangdong, China (e-mail: vampire_cn@163.com); **KAI WANG**, School of Biological Sciences, Washington State University, Pullman, Washington, USA (e-mail: kai.wang@email.wsu.edu).

***PHALOTRIS MATOGROSSENSIS* (Mato Grosso Burrowing Snake). DIET.** Ophiophagy is very common in some snakes, but uncommon in others, and rare in *Bothrops* spp., with only a few records (e.g., Martins and Gordo 1993. Herpetol. Rev. 24:151–152; Oliveira and Martins 1996. Herpetol. Rev. 27:22–23). *Bothrops moojeni* occurs in the Cerrado domain in central and southeastern Brazil (Leloup 1984. Acta Zool. Pathol. Antverp. 78:177–198; Borges and Araújo 1998. Rev. Brasil. Biol. 58:591–601). It is considered a dietary generalist; young feed on small mammals, frogs, lizards, snakes, birds, and centipedes, but adults prefer mammals (Andrade et al. 1996. J. Herpetol. 30:285–288; Nogueira et al. 2003. J. Herpetol. 37:653–659. França et al., 2008. Copeia 2008:20–36). *Phalotris matogrossensis* belongs to the family Dipsadidae and is distributed in semi-deciduous forest of São Paulo State, Brazil (Zaher et al. 2011. Biota Neotrop., pp. 67–81). During the necropsy of a *B. moojeni* specimen (SVL = 940 mm; tail length = 150 mm) captured in Castilho county, in northwestern São Paulo, Brazil, we found in its stomach a *P. matogrossensis* (SVL = 263 mm; tail length = 180 mm). The prey was intact, indicating a recent predation event. This is the first record of *B. moojeni* preying on *P. matogrossensis*.

DIANNE CASSIANO DE SOUZA (e-mail: dianne_cassiano@hotmail.com), **DRAUSIO H. MORAIS**, and **REINALDO JOSÉ DA SILVA, UNESP**, Univ. Estadual Paulista, Campus Botucatu, Instituto de Biociências, Departamento de Parasitologia, Botucatu, São Paulo, Brazil.

***PSEUDOBOA NIGRA*. DIET.** *Pseudoboa nigra* is a nocturnal, terrestrial snake with a wide distribution in South America (Peters and Orejas-Miranda 1970. Bull. U.S. Nat. Mus. 297:1–347; Gaiarsa et al. 2013. Pap. Avul. Zool. 53:261–283). In terms of diet, it is considered a lizard specialist, rarely consuming other types of food (Gaiarsa et al., *op. cit.*). In this note we present data on stomach contents of an adult male *P. nigra* (SVL = 597 mm; tail length = 225 mm; 118.5 g) collected by one of us (CFDR) on 8 November 1999 at 2200 h in the "restinga" habitat of Grussaí (21.683333°S, 41.030556°W; datum WGS84), municipality of São João da Barra, state of Rio de Janeiro, Brazil. After dissection, we found three empty squamate egg shells (length 17.6–19.5 mm; width 7.8–9.3 mm) and the digested remains of a scincid lizard (*Mabuya* sp.). It was not possible to identify the skink to species, but two species of *Mabuya* occur in the area: *M. agilis* and *M. macrorhyncha* (Vrcibradic and Rocha 2002. Rev. Bras. Zool. 19:77–83). The snake was deposited at the reptile collection of the Museu Nacional, Rio de Janeiro, as MNRJ 24638.

Skinks in the genus *Mabuya* have not been previously reported as prey of *P. nigra*, and the present record thus adds a new prey species for this snake. The squamate eggs found in the gut could not have been secondarily ingested with the skink, because *Mabuya* spp. (*sensu* Mausfeld et al. 2002. Zool. Anz. 241:281–293) are viviparous, and thus they must have been consumed directly. Squamate eggs have been previously reported in the diet of *P. nigra* (Orofino et al. 2010. Phyllomedusa 9:53–61; Mesquita et al. 2013. Pap. Avul. Zool. 53:99–113.), suggesting that occasional oophagy may not be uncommon in this species.

ALEXIA EISFELD (e-mail: alexia_magalhaes@hotmail.com), **DAVOR VRCIBRADIC** (e-mail: davor.vrcibradic@gmail.com), Departamento de Zoologia, Instituto de Biologia, Centro de Ciências Biológicas e Saúde, Universidade Federal do Estado do Rio de Janeiro, Av. Pasteur 458, Urca, 22240-290, Rio de Janeiro, RJ, Brazil; **CARLOS FREDERICO D. ROCHA**, Departamento de Ecologia, Universidade do Estado do Rio de Janeiro, Rua São Francisco Xavier 524, Maracanã, 20550-011, Rio de Janeiro, RJ, Brazil (e-mail: cfdrocha@ gmail.com).

***SISTRURUS CATENATUS CATENATUS* (Eastern Massasauga). DIET.** On 11 June 2013, on the property of the Camp Grayling Army and Air National Guard joint maneuver training base, Kalkaska, Co., Grayling, Michigan, USA, we captured a male *Sistrurus c. catenatus* (mass = 156.8 g without prey item). While releasing the snake at approximately 1100 h the following day, it regurgitated a partially-digested bird (mass = 13.2 g) that was likely swallowed headfirst. The head was the most digested portion and the rest of the body was largely intact, indicating that the bird had recently been consumed (Fig. 1).

To identify the species of bird, DNA was extracted from a tissue sample using a Qiagen DNeasy kit. Quality of DNA was

FIG. 1. A nestling *Toxostoma rufum* (Brown Thrasher) regurgitated by a male *Sistrurus c. catenatus* (Eastern Massasauga).

PHOTO BY KEITH GELUSO

FIG. 1. A *Sistrurus catenatus tergeminus* with a unique dorsal pattern photographed on a gravel road in northwestern Russell Co., Kansas.

assessed by running 2µl of genomic DNA on a 2% agarose TAE gel. Polymerase chain reaction (PCR) was carried out in 10µl amplification reactions for a 548-bp fragment of cytochrome oxidase using conserved avian mitochondrial primers and conditions outlined in Lovette and Rubenstein (2007. Mol. Phylogen. Evol. 44:1031–1056). BLAST searching returned a 99% match to *Toxostoma rufum* (Brown Thrasher). The *T. rufum* (GenBank accession number KF959632) has been deposited at Indiana University-Purdue University Fort Wayne, located in Allen Co., Fort Wayne, Indiana, USA. The mass of adult *T. rufum* ranges from 61–89 g (allaboutbirds.org; accessed 18 Jan 2014). Due to the relatively low mass and the presence of pin feathers from the regurgitated specimen, the bird is presumed to be a nestling. To our knowledge, this is the first recorded account of *T. rufum* in the diet of *S. c. catenatus*.

Adult *S. c. catenatus* primarily prey upon rodents but will also feed on several other taxa, including birds and bird eggs (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, Washington, DC. 668 pp.). Given the multiple accounts of avian species consumed by *S. c. catenatus*, we believe birds may be opportunistically taken as a food source in its diet more frequently than currently recognized.

We thank Amanda Talaba, Mark Jordan, and Bruce Arnold for assistance. Funding was provided by the Michigan Department of Military and Veterans Affairs and the Michigan Society of Herpetologists. All research was conducted under a Scientific Collector's permit from the Michigan Department of Natural Resources and an approved protocol from the Purdue University Animal Care and Use Committee.

SASHA J. TETZLAFF (e-mail: tetzsj01@ipfw.edu), **MICHAEL J. RAVESI** (e-mail: ravemj01@ipfw.edu), and **BRUCE A. KINGSBURY** (e-mail: kingsbur@ipfw.edu), Department of Biology, Indiana University-Purdue University Fort Wayne, 2101 E. Coliseum Boulevard, Fort Wayne, Indiana 46805, USA.

***SISTRURUS CATENATUS TERGEMINUS* (Western Massasauga). ABERRANT PATTERN.** *Sistrurus catenatus* generally has a ground color of light gray to light brown with a series of large dark brown blotches down the center of the back before becoming cross bands towards the tail (Ernst and Ernst 2011. Venomous Reptiles of the United States, Canada, and Northern Mexico. Vol. 1. John Hopkins Univ. Press. Maryland. 352 pp.). Three rows of smaller brown to black spots occur on each side of the body (Ernst and Ernst 2011, *op. cit.*). Variation in ground and blotch coloration is known (e.g., Woodburne 1956. Copeia 1956:125–126) as well as variation in number of dorsal blotches that range from 21 to 50 with a mean of 40 (Ernst and Ernst 2011, *op. cit.*). Few reports document major differences in dorsal blotching patterns of *S. catenatus*, but melanistic, albinistic, and a partially striped individual have been documented (Lardie and Lardie 1976. Bull. Oklahoma Herpetol. Soc. 1:40; Harris 2006. Bull. Maryland Herpetol. Soc. 42:181–183; Ernst and Ernst 2011, *op. cit.*).

On 2 October 2013, we observed and photographed an aberrantly patterned *S. catenatus* on 182nd Street on the southern end of a stretch between Saline River Road and Luray Road, Russell Co., Kansas, USA (Fig. 1). This individual lacked the familiar pattern but instead had relatively few, but paired, elongated blotches along more than half the total length of the snake. Towards the tail, blotches were single, ending with one elongated blotch that comprised about the last quarter of the total length. The characteristic three rows of smaller spots on the sides of *S. catenatus* were completely absent. Such a unique pattern of blotching appears rare and has not been documented previously in *S. catenatus* to our knowledge.

In northern Oklahoma, a partially striped individual was collected in Major Co. in 1973 (Lardie and Lardie 1976, *op. cit.*). On its posterior end, the young snake (236 mm SVL) had two dorsal stripes that measured 15 and 30 mm in length followed by four close-set blotches that preceded the rattle. No mention was made of any unusual lateral blotches or their absence.

We thank Curtis J. Schmidt for verifying the species identification and reviewing an earlier version of this manuscript.

R. ARIC BUERER (e-mail: buererra@lopers.unk.edu), and **KEITH GELUSO** (e-mail: gelusok1@unk.edu), Department of Biology, University of Nebraska at Kearney, Kearney, Nebraska 68849, USA.

***STEGONOTUS CUCULLATUS* (Slatey-grey Snake). MORTALITY.** *Stegonotus cucullatus* is a medium-sized mostly nocturnal terrestrial colubrid snake restricted to the northern parts of the Northern Territory and Queensland, Australia (Cogger 2014. Reptiles and Amphibians of Australia, 7th ed. CSIRO Publishing, Collingwood, Victoria, Australia. 1033 pp.); it is one of few endemic Australian snake species reported to consume adults of the invasive exotic bufonid anuran *Rhinella marina* without mortal effect from its skin toxins (e.g., Phillips et al. 2003. Conserv. Biol. 17:1738–1747). This note reports an instance of mortality to a *S. cucullatus* as a result of attempted predation on *R. marina*.

On 30 April 2009 (i.e., in mid-autumn, toward the end of the "wet" season) at an aquaculture facility at 100 Mahaffey Road, Howard Springs, ~23 km E of Darwin, Top End of the Northern Territory, Australia (~12.5165°S, 131.0556°E, datum GDA94; elev. 45 m), DW found a dead adult (total length ~1.1 m) *S. cucullatus* disposed in a series of irregular curves with a dead small adult (SVL = ~60 mm) *R. marina* in its mouth (Fig. 1), in an open grassy

PHOTO BY DAVID N. WILSON

FIG. 1. Dead adult *Stegonotus cucullatus* with partly swallowed dead *Rhinella marina*, Howard Springs, Northern Territory, Australia.

area between aquaculture pools. The head, neck, forelimbs, and anterior body of the *R. marina* had been swallowed by the *S. cucullatus*, and several red mymicine ant workers ~4 mm length, exotic *Solenopsis geminata*, were scavenging on the carcasses. On the basis of condition of the dead animals, it was estimated that mortality had occurred approximately 45 min prior to observation. Habitat in the vicinity comprised a cleared area in former Tropical Monsoon Woodland with aquaculture pools and shadehouses used for cultivation of aquatic plants and aquarium freshwater fish, sheds, and a human dwelling.

This is the first published report of mortality to *S. cucullatus* as a result of attempted predation on exotic *R. marina*; however, several similar cases have been observed. IJM has frequently observed *S. cucullatus* constricting and killing adult *R. marina*, variously swallowing, rejecting, or occasionally choking on prey, in many cases with their heads becoming coated with the toxic exudate from the parotoid glands of the prey. The snakes have appeared to suffer no ill effect from exposure to such large quantities of the exudate, although they wipe it off on the substrate after the interaction (IJM, unpubl. data). As a predator defense, adult *R. marina* inflate the body to a much greater extent than large adults of sympatric endemic anurans, and have more rigid skeletons (pers. obs.). We hypothesize that mortality in *S. cucullatus* reported here and in other similar cases with adult *R. marina* prey could be due to asphyxiation, rather than toxicity.

Anecdotally, there was a large reproductive population of *S. cucullatus* on the property where the above interaction was observed prior to colonization by exotic *R. marina*; however, since the colonization of *R. marina* the snakes are now rare, as is also the case with the large agamid lizard *Chlamydosaurus kingii*, the large varanid lizard *Varanus panoptes*, and several other endemic vertebrate species on the property (DNW, unpubl. data). Similar trends have also been surmised for the wider region (G. Sawyer, pers. comm.).

We thank Graeme Sawyer, Regional Coordinator (Darwin), Stop The Toad Foundation, for personal communication of the effects of *R. marina* colonization on endemic vertebrate fauna in the Northern Territory, and Alan N. Andersen and Ben Hoffmann of the Tropical Ecosystems Research Centre, C.S.I.R.O. Ecosystem Sciences, Winnellie, Northern Territory, for identification of the scavenging ants.

***THAMNODYNASTES PALLIDUS* (Amazon Coastal House Snake). REPRODUCTION.** *Thamnodynastes* is a South American genus with viviparous reproduction (Manzanilla and Sanchez 2005. Mem. Fund. La Salle Cien. Nat. 161-162:61–75). *Thamnodynastes pallidus* is a terrestrial and nocturnal species distributed over Bolivia, Colombia, Venezuela, the Guianas, and Brazil that inhabits forested ecosystems in the Amazonia and Atlantic forest biomes (Bailey et al. 2005. Phyllomedusa 4:83–101). Herein, we present possibly the first reproductive report for female *T. pallidus*. On 26 September 2008, in Salvador, State of Bahia, Brazil, a female (SVL = 320 mm, tail length = 130 mm; CHECOA 2673) was captured at the Jardim Botânico do Salvador, a small ombrophilous forest remnant (12.926733°S, 38.425037°W, datum WGS84; elev. 51 m). After examination of oviducts in the laboratory, we observed two oviductual eggs (21.3, 23.0 mm) and no ovarian follicles. On 12 July 2013 another female (SVL = 293 mm, tail length = 119 mm; CHECOA 2963) was captured at the Parque Metropolitano de Pituaçu, a large ombrophilous forest remnant (12.949936°S, 38.413887°W, datum WGS84; elev. 33 m). This specimen contained six ovarian follicles on the right side (≤ 3.4 mm) and four follicles on the left side (≤ 1.9 mm). Animals were collected under SISBIO permit Nº 23355-2 and deposited at the herpetological reference collection at the Centro de Ecologia e Conservação Animal, Universidade Católica do Salvador.

***THAMNOPHIS PROXIMUS PROXIMUS* (Orange-striped Ribbonsnake). DIET.** The diet of *Thamnophis proximus* consists mainly of fishes and amphibians, with anurans being more often reported than salamanders (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Institution, Washington, DC. 668 pp.). On 3 April 2014, at 1215 h, we captured an adult female *T. p. proximus* (SVL = 63.8 cm; 60.8 g) that was basking in a shrub, approximately 1 m off the ground, at the Tara Wildlife Refuge (private), Vicksburg, Warren Co., Mississippi, USA. The snake had recently fed, as indicated by a large bulge in its stomach, and upon palpating, the snake regurgitated an adult male *Anaxyrus fowleri* (Fowler's Toad). To the best of our knowledge, this is the first documentation of *A. fowleri* in the diet of *T. proximus*.

***TRIMERESURUS BORNEENSIS* (Bornean Palm Pit Viper). DIET.** *Trimeresurus borneensis* is a pitviper endemic to the island of Borneo. The species is considered common throughout its range and inhabits lowland and submontane forested areas up to 1130 m in elevation. *T. borneensis* feeds primarily on small mammals and birds; although they are suspected to feed on frogs and lizards as well, this behavior has never been documented (Das 2011. A Photographic Guide to the Snakes and Other Reptiles of

FIG. 1. *Trimeresurus borneensis* after regurgitating a *Draco maximus* in Sabah, Malaysian Borneo.

Borneo. 2nd ed. New Holland Publishers Ltd., London, UK. 144 pp.). Here, we provide the first documented observation of predation by *T. borneensis* on a lizard (*Draco maximus*).

At 1809 h on 2 February 2013, a male *T. borneensis* was encountered in the foothills of Mount Kinabalu in primary hill forest, Sabah, Malaysian Borneo. The individual was 4 m from a small stream (6.056498°N, 116.703682°E, datum WGS84; elev. 490 m). The snake had partially ingested a large gliding lizard (later identified as *D. maximus*), but regurgitated the lizard in response to our presence (Fig. 1).

We thank Tom Hewitt, owner of Lupa Masa Jungle Lodge for the use of the site, and Indraneil Das for identification verification. For ZRC voucher numbers we thank Kelvin K. P Lim.

***TRIMERESURUS STEJNEGERI* (Stejneger's Green Pitviper). DIET.** *Trimeresurus stejnegeri* is a viperid snake found throughout Taiwan and much of Southern Asia. Two stomach content analysis studies (Mao 1970. Herpetologica. 26:45–48; Creer et al. 2002. Zool. Sci. 19:907–913), including a combined total of 526 specimens of *T. stejnegeri* from throughout Taiwan, demonstrated that they prey on a variety of small terrestrial animals including frogs, lizards, rodents, and some arthropods. However, no references could be found providing examples of them preying upon other snakes. Thus, to our knowledge, this observation of ophiophagy in *T. stejnegeri* is novel to the understanding of the pitviper's ecology.

At 2117 h on 26 August 2013 (23°C) an adult *T. stejnegeri* (estimated total length = 700 mm) was observed consuming an adult *Amphiesma sauteri* (estimated total length = 500 mm) vent-first (Fig. 1A). The event was observed within old growth forest along the Bibù Cross-island Highway, southeast of Balíng, Taoyuan County, Taiwan, R.O.C. (24.66380°N, 121.40095°E, datum WGS84; elev. 797 m). When first encountered, the *T. stejnegeri* had already clamped its jaws crosswise on the cloacal section of the *A. sauteri*, but had not yet begun to swallow it. Both snakes were at street level on the concrete curb of the mountain road with the *A. sauteri* alternately trying to crawl away from the *T. stejnegeri* or trying to anchor itself on the embankment or curb to resist

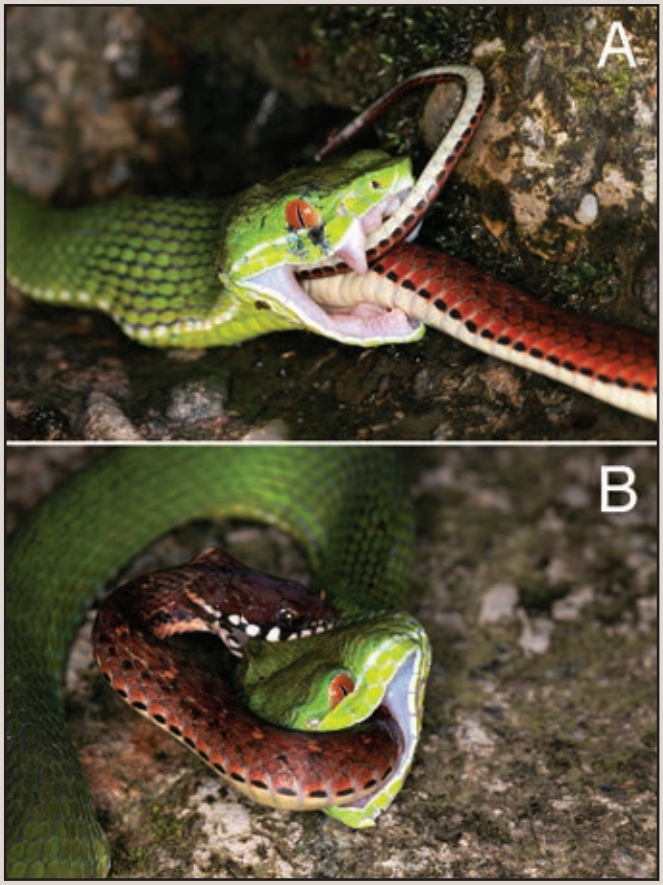

FIG. 1. A) *Trimeresurus stejnegeri* preying upon an *Amphiesma sauteri*, vent first. B) *Amphiesma sauteri* attempting to defend itself from the predatory *Trimeresurus stejnegeri*.

being eaten. By 2125 h the *T. stejnegeri* had managed to bend the *A. sauteri's* tail back against its body and begun to swallow the posterior portion of the *A. sauteri*. For the next 20 min, the *T. stegnegeri* slowly swallowed the *A. sauteri*, working its way up the length of the *A. sauteri*'s body, with the *A. sauteri* actively resisting for the entire battle. In a final act of defiance, the *A. sauteri* attempted to defend itself by biting the *T. stegnegeri*'s head (Fig. 1B). At 2145 h, only the *A. sauteri*'s head and perhaps 2 cm of neck were still visible outside the *T. stejnegeri*'s jaws. With the *A. sauteri*'s jaws clamped down on the T. *stejnegeri*'s head, the *T. stejnegeri* climbed the curb and retreated into a small hole in the embankment.

In addition to being useful to field biologists, field guides are valuable tools for disseminating information among non-scientists. They also often help decision-makers to identify areas of high biodiversity. Although the Neotropical realm probably harbors the world's greatest biodiversity, the amphibian species richness of many South American countries is not well understood by the general public because synoptic overviews of their batrachofauna are lacking. Field guides to the herpetofauna of the Guiana Shield are scarce despite the fact that the region is characterized by high levels of diversity and endemism, with some of the most iconic herpetofaunal representatives of the Neotropics (e.g., *Dendrobates tinctorius* [Cuvier, 1797]). This situation is exacerbated by incomplete sampling in several parts of the region and by the recognized existence of numerous species waiting to be named. However, a few field guides from some areas within the Guiana Shield are available (e.g., Lescure and Marty 2001; Lima et al. 2006, 2012; Kok and Kalamandeen 2008; the three latter downloadable for free).

Although Suriname was one of the first South American countries to be scientifically explored (Hoogmoed 2013), no compendium of information about the country's batrachofauna was available until recently. Most information is scattered across the scientific literature, which is often difficult, if not impossible to obtain for the local population, amateur naturalists, and visiting tourists.

Amphibians of Suriname by Ouboter and Jairam (2012) is an attempt to remedy this issue, and the authors certainly have to be acknowledged for their efforts. This being said, neither author is known for his experience in amphibian taxonomy and/or biogeography, and most herpetologists working in the Neotropics will probably start reading their book with circumspection. My own reading of Ouboter and Jairam's volume highlights a considerable number of mistakes, including some that I feel necessary to correct in this review.

Amphibians of Suriname is the first volume in the series *Fauna of Suriname*, produced by the well-known publishing group Koninklijke Brill NV with the support of NCB Naturalis (the former Rijksmuseum van Natuurlijke Historie, RMNH, Leiden, The Netherlands). The book is printed on acid-free paper and the binding of my hardback copy seems to be of high quality. The volume totals 376 pages including the preface and three indexes (subject, common names, and taxonomic), and is illustrated by 309 figures, 204 of which are color photographs, and 107 distribution maps (without indication of geographical coordinates). The book is divided into nine main sections. An Introduction (less than 2 pages); "Geography of Suriname" (eight pages); "Methods" (four pages); accounts of the 107 species said to occur in Suriname (316 pages), including the description of two new species and two new subspecies; a two page-section about the amphibian taxa that may occur in Suriname; "Zoogeography" (four pages); a section about conservation of the amphibians in Suriname (six pages); and finally a bibliography (nine pages), followed by a five-page appendix dealing with recent nomenclatural changes.

Although the authors complain in their introduction that no guide to the amphibians of the area (i.e., the Guiana Shield) is available in a language accessible to the Surinamese, the text they provide is written in rather poor English and was obviously not checked by a native English speaker before publication. In addition, the authors seemingly missed a field guide to the amphibians of Kaieteur National Park, located in the neighboring Guyana (Kok and Kalamandeen 2008), which is written in English and deals with many species present in Suriname. Unfortunately, this is not the only important reference missing. The lack of identification keys, even for families or genera, also comes as a surprise in a book intended as a field guide. Identifications can only be made by comparing photographs (many of problematic identification or poor quality, see below) and brief, often incomplete descriptions, which is inconvenient in the field. The lack of a glossary, which is always very useful to non-specialists, is also regrettable.

The Introduction mainly aims at providing a brief history of herpetological research in Suriname, and the current state of knowledge of the number of amphibian species recorded from the country. The introduction does not mention expeditions to collect herpetofauna by Marinus S. Hoogmoed in 1974 and 1975 (throughout Suriname), and in 1979 (Tafelberg) (M. Hoogmoed, pers. comm.). The material collected during these expeditions has been deposited in the RMNH, Leiden. Neither is fieldwork (1975, 1980, 1986) by personnel of the American Museum of Natural History (AMNH, New York) in Suriname mentioned. In their figure 1 the authors present a graph showing the number of species known from Suriname over the years, however the legend

explains it as the rate of descriptions of *new species* of amphibians for Suriname which, of course, would be represented by a radically different graph.

The section "Geography of Suriname" briefly explains and illustrates the geology, geography, climate, hydrology, and different types of macrohabitats found in the country. The map of Suriname represents the country borders as claimed by the Surinamese government, but not as recognized by the international community (Anderson 2003), which poses problems with some species distributions (see below).

In "Methods" the authors mainly explain how to use the book, list localities explored between 1988 and 2010 by P. E. Ouboter, and briefly overview collecting methods. The authors state "In addition to direct observations and collecting, the amphibian collections at NCB Naturalis (Leiden Natural History Museum, Netherlands) and the National Zoological Collection of Suriname [NZCS] form a solid base on amphibians of Suriname." Later on the authors state "The distribution in Suriname is based on all distribution records available," which are said to include the collections of the NZCS and the RMNH, as well as the literature and their own observations. However, as is evident from several maps, many localities of RMNH specimens collected by M. Hoogmoed between 1968 and 1990 have not been incorporated. This is especially evident in the map of *Pristimantis marmoratus* (Boulenger, 1900) (fig. 288, p. 311), a species said to be known only from three localities and thus considered rare in Suriname. However, specimens identified as belonging to that species were collected in dozens of localities in Suriname in large numbers by M. Hoogmoed (pers. comm.), and *P. marmoratus* as currently understood (but see remarks in Kok and Kalamandeen 2008, Fouquet et al. 2013, and Kok 2013) could therefore be one of the most abundant species in the rainforests of Suriname. Indeed, the incomplete use of available data has resulted in several erroneous conclusions being drawn in the conservation portion of the field guide. Apart from the general statement of the authors about the material examined, there is no listing of the material used to compile the book. Similarly, no material used for making the maps is mentioned, except for some of the taxa described as new. This in itself is understandable, but it makes it difficult to check identifications, especially in the light of the mistakes the field guide contains. Given the many misidentifications made by the authors (see below) one might wonder which occurrence records may be fully trusted. Finally, no information is provided on the methods used to analyze the vocalizations of the new species described in the book.

The species accounts section unfortunately contains a large number of problems, of which I will here discuss only the most obvious and important ones. As a first remark, describing new taxa in a field guide is not advisable because field guides are often not properly peer-reviewed and their format usually prevents detailed descriptions. The descriptions of *Anomaloglossus leopardus* and *A. surinamensis* are very brief and far from the current standards of new species descriptions in herpetology. Sexes of holotypes and paratypes are not provided, and diagnoses are limited to comparison with two (*A. leopardus*) to three (*A. surinamensis*) congeneric species. Because nothing is stated about the methods used to analyze the advertisement calls, one might wonder how the authors measured the note length and note intervals in the calls illustrated on p. 41 (fig. 34). Spectrograms show significant background noise, which probably made it very difficult to decide where the note begins and ends. Temperatures at which calls were recorded are not mentioned. These data are especially important since the authors use temporal characteristics to discriminate between the calls of *A. surinamensis* and *A. degranvillei* (Lescure, 1975).

Each taxon account begins with the scientific name of the species and the authorship. Species authors are systematically placed between parentheses, which is incorrect for many of them (authors should be placed between parentheses only when the genus name changed after the original description). The "Short descriptions" indeed are rather short and often do not serve to identify specimens correctly. The "Distribution" section in several cases contains mistakes, and the "Habitat" section is often very brief, the authors apparently having not surveyed the extensive literature that provides a wealth of data on this aspect for several of the species treated. There is usually no information about tadpole morphology and advertisement call of the species.

Regrettably, a number of photographs are wrongly identified. Many show preserved specimens that do not provide a good idea of the species (e.g., fig. 299 of *Microcaecilia rabei* [Roze and Solano, 1963], several are from specimens from outside Suriname (which would not be a problem if the exact localities were mentioned), and the quality of some pictures is not good enough to allow easy identification in a field guide. One noticeable example of a problem related to a photograph is the illustration of "*Dendrobates tinctorius azureus*" on p. 107 (fig. 100). That subspecies is said by Ouboter and Jairam to be endemic to the Sipaliwini Savannah in Suriname. However, the photograph they use to illustrate that endemic subspecies is virtually the same as one provided by Naskrecki (2011: 234), showing a specimen that actually had been photographed in the Acarai Mountains of Guyana (locality confirmed by P. Naskrecki). Ouboter and Jairam wrongly report that the photograph was taken by Russell A. Mittermeier in the Sipaliwini Savannah. The authors thus illustrate an endemic subspecies stated to be only diagnosable based on coloration and a hunched back with a specimen presenting the same characteristics but coming from a neighboring country. In any case, it is surprising that the authors treat *D. azureus* Hoogmoed, 1969 as a subspecies of *D. tinctorius* without any argumentation. Wollenberg et al. (2006) synonymized *D. azureus* with *D. tinctorius*, and nobody has previously treated *azureus* as a subspecies.

The validity of the other two subspecies described as new in Ouboter and Jairam is also doubtful. There is no evidence indicating that *Atelopus hoogmoedi nassaui* is anything other than a color morph of *Atelopus hoogmoedi* Lescure, 1974 (purple specimens are also known from northern Brazil), or possibly of *A. barbotini* Lescure, 1981. Frost (2014) treats *Atelopus hoogmoedi nassaui* as a junior synonym of *Atelopus hoogmoedi*. I believe that the taxonomic status of *A. barbotini* and *A. hoogmoedi* needs to be clarified and that it is premature to assign the population from the Nassau Mountains to any of these taxa. In the same vein, there is no evidence for the validity of *Ameerega trivittata nassaui*, a case already discussed by Hoogmoed (1971a, b). Hoogmoed found no morphological differences between the green and the orange striped morphs, and during fieldwork in 1974 and 1975 noted a rather narrow transitional zone between the green morph and the orange morph on top of the Lely Mountains, where specimens were more yellowish (M. Hoogmoed, pers. comm.). Dendrobatid frogs are well known to show great variation in color and pattern so using these characters alone for taxonomic purposes is problematic. The distribution map of *Ameerega trivittata* (Spix, 1824) (fig. 87, p. 93) does not indicate which localities refer to *A. t. trivittata* or to *A. t.* "*nassaui*." Figure 91 (p. 97) does provide the distribution of *A. t.* "*nassaui*," but

for readers not acquainted with the topography of Suriname it will be difficult to decide where this area is located in the country. Ouboter and Jairam do not mention any of the publications (Hoogmoed, 1971a, b) that have already discussed the orange morph of *A. trivittata* and showed that recognition of a subspecies was not warranted. Moreover, the authors only provide localities in the area of the Nassau Mountains, but the orange morph is also known from a lowland area at the western foot of the Nassau Mountains and from the central part of the Lely Mountains, which in their southern part have green *A. trivittata*. Schouten (2008) mentioned a locality on the Suriname bank of the Marowijne River (possibly Amapoema, cf. Hoogmoed 1971a, b), but its precise location was not specified.

Rhinella granulosa (Spix, 1824) is reported from Suriname (p. 56) although Narvaes and Rodrigues (2009) restricted this name to toads from northeastern Brazil. These authors mention *R. merianae* (Gallardo, 1965) and *R. humboldti* (Gallardo, 1965) from Suriname, but these two putative species are morphologically very similar—potentially synonyms—and their taxonomic status should be confirmed. I would advise the use of the name *R. merianae* for the Surinamese population in accordance with former use of the subspecies names of Gallardo (1965) until the taxonomic status of *R. humboldti* is confirmed, e.g., by molecular data.

Hyalinobatrachium crurifasciatum Myers and Donnelly, 1997 (p. 78) is a synonym of *H. capellei* (van Lidth de Jeude, 1904) (Castroviejo-Fisher et al. 2011).

Eleutherodactylus planirostris (Cope, 1862) is reported for the first time from Suriname (p. 108) and claimed to be part of the Surinamese batrachofauna. Except for the photograph, Ouboter and Jairam do not document any vouchers to support their assertion or to clarify if the species has become established in Suriname.

Hypsiboas dentei (Bokermann, 1967) is also reported from Suriname for the first time (p. 144). No vouchers are reported and the two photographs illustrating the account are obviously not from Suriname (see also Hoogmoed 2013). Instead, Ouboter and Jairam apparently base this new record solely on the map in Lescure and Marty (2001), arguing that the southwesternmost locality of that species lies in Suriname, which is incorrect (Anderson 2003). It would have been better to mention this taxon in the section dealing with the species that may be present in Suriname (as did Hoogmoed 2013).

Scinax jolyi Lescure and Marty, 2001 is "provisionally" reported (pp. 176–178) from localities in the northeast of Suriname. However, Marinus Hoogmoed (pers. comm.) examined the specimen illustrated in figs. 167–168 (in the RMNH collections), directly compared it with three paratypes of *S. jolyi* and identified it as a female *S. nebulosus* (Spix, 1824). Fig. 165 also shows *S. nebulosus* and I come to the conclusion that the report of *S. jolyi* for Suriname is based on incorrect identifications (confirmed by A. Fouquet, pers. comm.).

Leptodactylus bolivianus Boulenger, 1898 is reported from Suriname (p. 224) although the correct name of the taxon in Suriname now is *L. guianensis* Heyer and de Sá, 2011 (Heyer and de Sá 2011).

Leptodactylus ocellatus (Linnaeus, 1758) is reported from Suriname (p. 250) although the correct name of the taxon in Suriname is currently *L. macrosternum* Miranda-Ribeiro, 1926 (Frost 2014). However, figures 236 and 238 do not illustrate *L. macrosternum* but rather likely represent *L. longirostris* and *L. fuscus*, respectively.

Chiasmocleis hudsoni Parker, 1940 is reported from Suriname (p. 272) apparently only on the basis of the holotype (and thus from Guyana, see comments in Peloso et al. 2014) since no additional locality is provided on the map. The type locality actually is further east in the headwaters of Kutari Creek (Hoogmoed 1973), on the border of Guyana and Suriname. Hoogmoed (2013) provides a photograph of a specimen collected on the airstrip at Sipaliwini, and there is more material in RMNH from the Rechter Kabalebo river collected in 1975 (M. Hoogmoed, pers. comm.).

Pipa arrabali Izecksohn, 1976 is synonymized with *P. aspera* Müller, 1924 on the basis of insufficient material and subjective arguments that are not convincing (p. 290). Thus, this synonymization should be rejected and the species *P. arrabali* remains on the list of Suriname species. Both species are well defined by Trueb and Cannatella (1986).

Two species definitely known from Suriname are not dealt with in the species accounts section of the book: *Microcaecilia grandis* Wilkinson, Nussbaum & Hoogmoed, 2010 (Wilkinson et al. 2010), and *Pseudopaludicola boliviana* Parker, 1927 (Hoogmoed 1979, as *P. pusilla*).

Additional problems with wrongly identified photographs are:

On p. 61, the "*Rhinella lescurei* (Fouquet, Gaucher, Blanc and Velez-Rodriguez, 2007)" in fig. 57 is a *Rhinella martyi* (Fouquet, Gaucher, Blanc and Velez-Rodriguez, 2007); the same is true of fig. 59 on p. 63.

On p. 75, the "*Cochranella geijskesi* (Goin, 1966)" in fig. 70 is a *Vitreorana oyampiensis* (Lescure, 1975).

On p. 77, the "*Vitreorana oyampiensis* (Lescure, 1975)" in fig. 72 is a juvenile *Hypsiboas*.

On p. 89, the "*Ameerega hahneli* (Boulenger, 1884)" in fig. 84 is an *Allobates femoralis* (Boulenger, 1884).

On p. 149, the "*Hypsiboas fuentei* (Goin and Goin, 1968)" in fig. 139 is *Hypsiboas crepitans* (Wied-Neuwied, 1824). The authors, however, mention that the former may be a junior synonym of the latter, but still provide a full species account with occurrence records.

On p. 161, the "*Osteocephalus buckleyi* (Boulenger, 1882)" illustrated in fig. 150 is most likely *O. taurinus* Steindachner, 1862.

On p. 209, the "*Phyllomedusa hypochondrialis* (Daudin, 1800)" in fig. 194 is actually *P. tomopterna* (Cope, 1868).

On p. 221, the "*Leptodactylus andreae* (Müler, 1923)" in fig. 206 likely is *Adenomera heyeri* Boistel, de Massary and Angulo, 2006.

On p. 233, the "*Leptodactylus hylaedactylus* (Cope, 1868)" in fig. 216 is likely *Adenomera andreae* (Müller, 1923). In the text (p. 222) the authors state that they could not distinguish between *A. andreae* and *A. hylaedactyla* (but they still provide a description and pictures for both taxa) and that they think *A. andreae* is a junior synonym of *A. hylaedactyla*, although they do not take formal taxonomic action.

On p. 317, the "*Pristimantis zeuctotylus* (Lynch and Hoogmoed, 1977)" in fig. 294 is a juvenile *Scinax boesemani* (Goin, 1966).

Some taxonomic changes occurred when the book was probably in press (e.g., *Amazophrynella minuta* [Melin, 1941] [Fouquet et al. 2012b, c]), or soon after its publication (e.g., in the genera *Osteocephalus* [Jungfer et al. 2013] and *Adenomera* and *Lithodytes* [both removed from *Leptodactylus*, see Frost 2014]); *Scinax trilineatus* (Hoogmoed and Gorzula, 1979) was synonymized with *S. fuscomarginatus* (Lutz, 1925) (Brusquetti et al. 2014), and these are not further discussed here.

The next section (p. 334) deals with seven amphibians that may be present in Suriname, but are not yet recorded or are "known from one specimen collected in the far past only." *Caecilia albiventris* Daudin, 1803 is probably a synonym of *C. tentaculata* Linnaeus, 1758 (Maciel and Hoogmoed 2011). *Anomaloglossus degranvillei* is likely endemic to French Guiana (see Fouquet et al. 2012a). The list could have been extended with some more recently described species from neighboring countries.

The section "Zoogeography" divides the taxa known to occur in Suriname into six groups (contents not listed, but figured in fig. 307) and species with a restricted distribution in Suriname are divided into five groups (Table 9), of which the group "restricted to bauxite capped mountains" can immediately be discarded, as all species in that group are known from other (lowland) localities as well, both in Suriname and elsewhere. Species reaching their limits in Suriname are also dubious, e.g., *Physalaemus ephippifer* (Steindachner, 1864) is said to reach its eastern limit in Suriname, but the species was described from Pará and occurs in northern Pará and in the surroundings of Belém as well. The authors apparently were aware of this distribution, because they mention "mouth of the Amazon" as part of its distribution, and that area is well east of Suriname.

The section "Conservation of Amphibians in Suriname" cannot be trusted because of the methodology used (simply counting specimens collected and localities recorded), because of the fact that the authors did not evaluate all material available in the collections they consulted for distribution data (see above), and because the authors have obviously misidentified several specimens.

The bibliography is not up to date, with many references missing (both old and recent ones).

The Appendix is a simplified (not critical) explanation of the nomenclatural changes proposed by Faivovich et al. (2005) and Frost et al. (2006).

In conclusion, Ouboter and Jairam's book unfortunately has inaccuracies that may mislead the reader and, because of the issues mentioned above, the volume is of limited interest to both professional and non-professional herpetologists.

Acknowledgments.—I am very grateful to Marinus Hoogmoed (Museu Paraense Emílio Goeldi, Brazil) and Antoine Fouquet (Centre National de la Recherche Scientifique Guyane, French Guiana) for sharing useful information and providing pertinent comments on a previous version of this book review. Thanks also to Piotr Naskrecki (Museum of Comparative Zoology, USA) for confirming my doubts.

Rosy Boas—Patterns in Time

Gerold Merker, Bob Montoya, and Randy Limburg. 2011. ECO Herpetological Publishing & Distribution, Rodeo, New Mexico (www.rosyboainfo.com). 184 pp. US $29.95. Softcover. ISBN 978-0-9832789-0-0; Hardcover US $69.95 (ISBN 978-0-9832789-1-7).

JEFF BOUNDY
Louisiana Department of Wildlife and Fisheries, PO Box 98,000, Baton Rouge, Louisiana 70898-9000, USA
e-mail: jboundy@wlf.la.gov

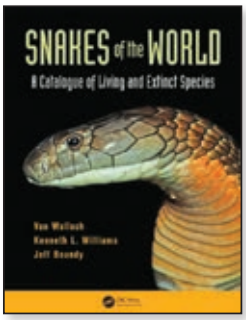
The title of my college geology text, *Rocks: Patterns in Time*, came to mind as I studied the cover of the present work. Rocks and Rosy Boas are two entities that seem inextricably associated over much of the American Southwest. The title led me to imagine panoramic vistas of rocky landscapes, eroding over eons as animals crept over them. Among those creatures were the "slow-moving and peaceful" Rosy Boas of the genus *Lichanura*—a genus dating from at least the late Miocene. The title suggests a dissertation on the evolution of boa color patterns, a potentially fascinating topic, with some populations evolving along habitat gradients and others in isolation. However, the authors state that their work "discusses proven technologies for the successful maintenance and captive breeding of Rosy Boas." My thoughts now disturbingly afflicted with memories of pine shavings saturated in rodent urine, I prepared for literary doldrums.

Though the stated primary focus of the book is Rosy Boas in captivity, the chapter on Captive Care occupies only 12 pages. The guidance for the care and propagation of Rosy Boas seems generic for most live-bearing snakes native to temperate climates, though the average hobbyist may not be aware of the miserly cycling of drinking water every three weeks. Topics discussed include proper housing, temperature control, propagation, feeding, diseases and parasites, and handling, each of which is illustrated by one or more color photographs. I was not aware that there was a technique to waking your boa, or that Rosy Boas will indeed bite under certain circumstances. I do not know what portions of text were composed by which author, but each seems to have a preferred cage temperature: 27–29°C is given on page 10, 25–31°C on page 13, and 25–29°C on page 14. At the end of the book there is a 22-page collection of photographs of unusually or uniquely colored boa "morphs." This pictorial spread is occasionally interrupted with boxes of text that ask such questions as "What is a Snowy Rosy Boa?" The authors add some history to the derivation of the morph lineages, which I gather are cultivated in captivity from off-colored, wild-caught boas.

The refreshing heart of the book, 130 pages, consists of what the authors term a "photographic journey to show how this beautiful reptile has adapted to so many locations." The journey has many stops—40 in California, 16 in Arizona, and 22 in Mexico. Nearly every stop is illustrated by a habitat shot and two or three boas. If you have a favorite spot for finding boas, it is probably mentioned in this book. I am familiar with a number of the localities, and have a perspective on the subtle changes in the habitat and boas one might encounter on a drive from Morongo Valley to Pioneertown, and across to Twentynine Palms. But, I fear that readers unfamiliar with the arid Southwest will not recognize the significance of many of the habitat and pattern morph associations, a situation which could have been improved by a locality map. The arrangement of locales used by the authors, however, does illustrate the gradual, often subtle shift in color pattern over often small geographic increments, illustrating the many ways that a simple theme of a pale snake with three stripes can vary from one place to another.

The book is not a taxonomic treatment and Rosy Boa subspecies are not mentioned (in fact, the words *Lichanura trivirgata* are absent). A map on page 23 shows the ranges of four classic subspecies, which are referred to as "forms," but are not further discussed. An unstated, and perhaps unintentional, theme of the book is the impossibility of assigning many populations of Rosy Boas to one of the traditional subspecies. The long photographic essay is itself a visual argument against the subspecies concept.

The book is nicely produced, 21 x 28 cm, on glossy paper stitched between stiff paper covers. It seems durable, and conveniently remains open when laid flat on its spine. Aside from dozens of scenic habitat photographs, there are 362 photographs of boas, 50 of boa heads and body sections, and 38 of other amphibian and reptile species that might be encountered while searching for Rosy Boas. Most of the boa shots appear to have been taken with use of a soft flash, which perfectly highlights the color and pattern of each snake. For me, the most interesting photographs are those of the "Colonet" Boa, the type "morph" of *Lichanura roseofusca*. Though described nearly 150 years ago, that odd coastal morph from which the name Rosy Boa derives has, to my knowledge, only now been adequately illustrated.



The back cover contains a promotional blurb about the book, emphasizing that it details the maintenance and propagation of boas resulting from over 100 years of combined experience by the authors. The condensed account of their indoor achievements is thorough and nicely illustrated. For some hobbyists, the boa ensconced in its cage of aromatic pine shavings is sufficiently satisfying. Fortunately for the field-oriented, the authors have also assimilated many years afield into a pictorial display of boas in their natural environment. Their visual achievement not only provides a spatial concept of Rosy Boa pattern variation, but

for many, like me, it recalls finger pads rubbed raw from turning granite rocks, and cholla spines embedded in awful places. The journey on which readers are taken is well worth the investment.

Snakes of the World: A Catalogue of Living and Extinct Species

Van Wallach, Kenneth L. Williams, and Jeff Boundy. 2014. CRC Press/ Taylor and Francis, Boca Raton, Florida (http://www.taylorandfrancis.com). xxvii + 1209 pp. Hardbound. US $142.00. ISBN: 978-1-4822-0847-4; eBook (VitalSource format) $104.97. ISBN 9781482208481.

PETER UETZ, RACHEL DAVISON, JACQUELINE ELLIS
Center for the Study of Biological Complexity, Virginia Commonwealth University, Richmond, Virginia 23284, USA
e-mail: uetz@vcu.edu

Just 15 years ago most textbooks in biology, zoology, or even herpetology claimed that there are ~6000 reptile species (e.g., Becher 1998; Margulis and Schwartz 1998). Some may still use this number today. We do not know where this number came from originally, but we suppose someone must have guessed it in the 1960s when it was about right. In fact, it was only in the 80s and 90s that some of the first "complete" species lists were published, such as Frank and Ramus (1995) who listed ~6700 species of reptiles. This was clearly a step forward but most of these books suffered from a number of shortcomings. Most importantly, they did not provide any references to the scientific literature where the names or the taxonomy came from. Hence one of us [PU] started to compile his own list, partly based on Frank and Ramus (1995), which subsequently became the EMBL Reptile Database (Uetz and Etzold 1996).

Since then numerous checklists, atlases, and catalogs have been published, usually either based on geographic areas (such as *Reptiles and Amphibians of Australia* by Cogger 2014), or on taxonomic group (such as the TTWG turtle checklists, TTWG 2014). These works all represent important updates to the local or global faunas.

However, no book has ever tried to compile a comprehensive *and* annotated checklist of all snakes until Wallach et al. did so in their monumental new *Snakes of the World*. It is a species checklist listing all extant and extinct snake species, including their basic synonymy, type information (primary type and type locality), distribution (by country and subdivisions such as states), and references (sample pages are available on Google Books and other sites). The book lists 3509 extant and 274 extinct species on 794 pages. On top of that it includes a bibliography of 306 pages (with an estimated 11,000 references!), resulting in a total of 1209 pages. The authors also included 26 pages on *species inquirenda*, that is, species of unclear status, and also organized references to the literature geographically on 13 pages. Overall, the book provides a wealth of information essential to any snake taxonomist or layman who is seriously interested in snake taxonomy.

Should you buy this book if you are a "mere" snake enthusiast? It depends. If you like to have six pounds of paper sitting on your bookshelf or your desk you should. Wallach et al. provide a permanent record of snake taxonomy as of December 2012. Unfortunately, this is also the time when the problems began, including for the very first species listed in the book: *Acalyptophis peronii* Duméril 1853. Within days of the deadline that Wallach et al. had set for themselves Sanders et al. (2012) published a phylogenetic analysis of the sea snakes in which they suggested the synonymization of *Acalyptophis* with *Hydrophis*, thus renaming the species *Hydrophis peronii* and rendering the Wallach book obsolete, even before typesetting had begun. You will not find the name *Hydrophis peronii* in the book, nor the index, which does list all synonyms. Luckily, the index distinguishes current names from synonyms by bold and regular typeface, respectively. Unfortunately, in many cases this was not properly copyedited, so that many valid species are listed in regular typeface. Similarly, while extinct species are listed in alphabetical order together with extant species, they are distinguished in the text with a dagger (†) but not in the index. In other words, if you would like to look up more than a few species, e.g., a list of all extinct species, you will have to do a lot of manual searching.

In fact, searching is what makes the book truly difficult to use. If you want to look up a single species or genus you are fine. But as soon as you try to do a more complex search, such as for the rattlesnakes of Mexico, it will become pretty difficult if not impossible. Luckily, there is an eBook version, but it is in a proprietary format of CRC Press, called VitalSource. We have not used the eBook but assume that searching and highlighting is possible as in most eBooks. However, we do not know if this gives you any added benefit, such as linked references from within the text. In the printed book even looking up a few references quickly becomes a drag. Many species entries have several dozen references in the format "Bocage, 1895" which you have to look up one by one in the bibliography, requiring a lot of thumbing back and forth.

Even if the book is up to date until 2012 or early 2013, many of the taxonomic decisions are difficult to track down. For instance, Wallach et al. recognize the genus *Taphrometopon*. They cite Zaher et al. (2012) as source but that paper does not even mention the genus (although Zaher et al. do show three species of *Psammophis* in a tree that correspond to what Wallach apparently considers as the *Taphrometopon* clade).

Similarly, Wallach et al. cite Zaher et al. (2012) as source for the synonymy of many other genera, such as *Rhadinophis* and *Rhynchophis*. Again, Zaher et al. did not formally synonymize the two genera although they do show that *Rhynchophis boulengeri* nests within *Rhadinophis*. Another example is *Rhynchophis prasinus* (now again *Gonyosoma prasinus*). Wallach again cites Zaher et al. (2012), but they show *prasina* in their tree as *Rhadinophis*. In fact, Zaher's analysis is overused; according to Wallach et al. *Stenophis* is a "synonym of *Lycodryas fide* Zaher et al., 2012." However, it was Nagy et al. (2010) who synonymized *Stenophis* with *Lycodryas*.

We could quote many other examples in which the origin of taxonomic decisions is not obvious. We will mention just one: *Xenochrophis vittatus* is placed in the genus *Ceratophallus* (p. 152). Wallach et al. cite Dubey et al. (2012), Guo et al. (2012) (misspelled as Gou), and Zaher et al. (2012) as sources but none of them even mentioned that name (although all of them showed *X. vittatus* in their trees). Hence it is usually unclear who used a combination for the first time. In other words, Wallach et al. often draw conclusions from papers which were not drawn by the authors of those papers.

It is hard to do an overall evaluation of the completeness of the species list without a machine-readable version. One

immediately obvious omission is the absence of subspecies. Wallach et al. simply elevated all subspecies to full species or put them into the synonymy of valid species. We would argue that this unnecessarily conceals the diversity of snakes. For instance, the Reptile Database currently (December 2014) contains 433 snake species that have a total of 917 subspecies (which is the main reason why the number of species in the database—3522—only slightly larger than those in the book, at 3509).

We wondered how many discrepancies exist between Wallach et al. and the Reptile Database. Besides the differences between species and subspecies counts, we compared the 518 snake genera in the database to the 539 listed in the book. Quite surprisingly, more than 130 genera showed differences in species numbers! Only at second glance was this less dramatic than the numbers suggest. As noted, the differences can mostly be explained by subspecies elevated to species level, and more importantly, by relatively few large-scale taxonomic rearrangements. For example, at least 30 genera have been either erected since 2012 or received new species. The genus *Acalyptophis,* as mentioned earlier, was synonymized together with another eight other genera with *Hydrophis* in one fell swoop (Sanders et al. 2012), and all of these genera are kept in the book. Carrasco et al. (2012) synonymized several genera (including *Rhinocerophis, Bothropoides,* and *Bothriopsis* and others) back into *Bothrops.* Similarly, Hedges et al. (2014) split up blind snakes and erected another eight new genera (obviously too late for the book), a nomenclatural act that was partly reversed by Wallach himself recently (Pyron and Wallach 2014). As a last example, *Vipera, Trimeresurus,* and *Naja* were split up by various authors (including Wallach et al.) into many genera whereas the Reptile Database still uses subgenera for these. The bottom line is that pretty much all the species (described up to 2012) are both in the book and the Reptile Database although there may be different generic assignments or different levels (species vs. subspecies). The discrepancies may be confusing to many users, given that many field guides rightfully use subspecies to distinguish morphologically different forms (even though in many cases morphology does not match their phylogeny, but that's another story). We found only a few species missing from the book, such as *Toxicocalamus mintoni* Kraus, 2009 and *Toxicocalamus pachysomus* Kraus, 2009.

To get a better comparison of species names, we compared the "A" section from the index to the Reptile Database. Surprisingly, we could not find about 20% of the species combinations in the database. Again, at second look, this often turned out to be a matter of spelling variants or combinations thereof. For instance, the index lists five spelling variants of *Walterinnesia aegyptia,* of which only one is the Reptile Database (which has yet another one that is not in Wallach's book). However, since the index also includes fossil species without being labeled as such we may have missed many of them when searching. Annoyingly, a number of names are misspelled in the index but not in the actual text, e.g., *Coniophouis* [= *Coniophanes*] *fissidens andresensis, Elphe* [= *Elaphe*] *anomala, Pseudoxenodar augusticeps* [= *Pseudoxenodon angusticeps*], etc.—and these are just some examples from the "A" section of the index, listed under their species epithets. The first example is especially annoying as *andresensis* is listed with *andresiana* and *andreoides* between *almawebi* and *Alopecion*—clearly out of alphabetical order.

Despite its numerous issues, the book is the only comprehensive resource on extinct snakes that we know of and the best available catalog of both extinct and extant snake names in print.

Orangutans and Gorillas Just Do Not Like Snakes

"We must concede that the Apes are malicious, cunning, choleric, vindictive, sensual, quarrelsome, irritable and peevish; on the other hand, we must take into account their cleverness, their good humor, their gentleness, their trust in, and kindness to Man, their amusing social qualities, their cheering earnestness, their courage and their readiness to stand by each other in case of need, even against superior enemies, and their inclination to play and tease. In one respect they even rise to greatness, and that is in their love for their offspring, their pity for the weak and defenseless, not only of their own family and kind, but even of other animals."

—Alfred E. Brehm, *The Animals of the World: Brehm's Life of Animals*, 1895

"It is certainly striking that, of all the mammals, only the apes and monkeys, our nearest relatives, show a dread of snakes. Possibly the common prejudice against these exquisite creatures is a dying inheritance from our far-off ancestors."

—Peter Chalmers Mitchell, *Centenary History of the Zoological Society of London*, 1929

". . . I took a stuffed and coiled-up snake into the monkey-house at the Zoological Gardens, and the excitement thus caused was one of the most curious spectacles which I ever beheld. Three species of Cercopithecus were the most alarmed; they dashed about their cages, and uttered sharp signal cries of danger, which were understood by the other monkeys. . . I then placed a live snake in a paper bag, with the mouth loosely closed, in one of the larger compartments. One of the monkeys immediately approached, cautiously opened the bag a little, peeped in, and instantly dashed away. Thus I witnessed what [Alfred E.] Brehm had described, for monkey after monkey, with head raised high and turned on one side, could not resist taking a momentary peep into the upright bag, at the dreadful object lying quietly at the bottom."

—Charles Darwin, *The Descent of Man and Selection in Relation to Sex*, 1871

The history of research on primate ophiophobia goes back almost two hundred years (see Burghardt et al. 2009, Table 1, for examples). Alfred Edmund Brehm, who created the word "Vivarium," was Director of the Hamburg Zoo from 1863 onward and founder of the Aquarium Unter den Linden (Berlin's main street) in 1869. Brehm (1895) mentioned that Captain Smitt had an Orangutan that lived on a ship for three months: "He was never heard to make but two different sounds; a feeble piping one, designed to express agitation, and a dreadful roar, resembling the lowing of a Cow, and denoting fear. Once he uttered the latter at sight of a Whale swimming near the vessel, and again when he caught sight of several Water Snakes that his owner brought from Java. The expression of his face never changed." (Fig. 1).

At the London Zoo and other institutions, P. Chalmers Mitchell and R. I. Pocock (1907) studied the fear of snakes by recording responses to snakes by many mammals and birds—they drew two major conclusions. The first was ". . . there is no such thing as a power of fascination possessed by snakes. Smaller birds and mammals are as inquisitive to a slowly advancing snake as to a slowly moving human hand directed toward them. Sudden or noisy movements elicit a flight response." The second point was that ". . . except in one group, animals have no specific fear of serpents. The vast majority of animals of course frogs, rats and mice, guinea-pigs, rabbits, ruminants, and birds, are totally indifferent to their presence, and even when a snake approaches them directly avoid it, just as they would a stick thrust at them." The excepted group was non-human primates. Corn Snakes, a Tree Boa, and small Reticulated Python were presented to monkeys at the Zoo. Most of the Old and New World monkeys showed varying degrees of threat or escape behaviors, although a few seemed unaffected by the presence of a snake. Baboons, including the Mandrill, ". . . were even more panic-stricken, jumping back in the greatest excitement, climbing as far out of reach as possible and barking." Gibbons were less fearful, which was attributed to their arboreal habits. Lemurs were curious when presented with snakes and advanced toward the reptiles, perhaps to feed upon them. There are reports (Goodman et al. 1993; Karpanty and Wright 2007; Headland and Greene 2011) of snakes such as Madagascan Tree Boas (*Sanzinia madagascariensis*) preying on lemurs so it is somewhat surprising that these primates did not flee.

Chimpanzees were frightened by snakes, except for one baby. These apes fled screaming to the highest reaches of their cages. Interestingly, large nematodes passed during defecation, when viewed by other chimps, elicited similar fear responses. Even earthworms caused a similar reaction, perhaps because of their cylindrical shape. However, not all chimpanzees are afraid of snakes. In the late 1950s, herpetologist Moody Lentz at St. Louis Zoo kept a pet Black Ratsnake at the reptile house. When the staff needed to shift the chimps to a new enclosure (and they refused to do so) someone suggested using a rubber snake to scare them. The rubber snake was presented and ignored. Moody then sent for his snake, and it was presented to the chimps, which started vocalizing and bouncing off the walls. Suddenly one of them ran over, grabbed the snake and beat it to a bloody pulp by bashing it repeatedly against the concrete floor (Lee Jackson, pers. comm.).

Source and Relevent Excerpts
WARWICK, J. E. 1832. The habits and manners of the female Borneo Orang-Utan (Simia Satyrus), and the male Chimpanzee (Simia Troglodytes), as observed during their exhibition at the Egyptian Hall, in 1831. The Magazine of Natural History (and Journal of Zoology, Botany, Mineralogy, Geology, and Meteorology) [London]. Vol. 5, May, 1832:305–309.
text from p. 308— second paragraph: "... The timidity of both animals was remarkable, they being exceedingly alarmed even at inanimate objects; a toy-dog, or a cast of one of their own species, that was in the room, if removed the least towards them, was sufficient to drive them to the farthest extremity of the apartment, in their most nimble, though not very quick, pace; and the fear exhibited by the female, at the sight of her deadly enemy, a boa constrictor, was most acutely evinced. It would appear as if they had not the power of distinguishing between the real and artificial, as a toy-snake shown to her produced the same results."
BETTANY, G. T. (Author of Zoology sections). 1884. Zoology. X. Man-like monkeys (continued)- The Gibbons. *In* The Universal Instructor or Self-Culture for all. Volume II, pp. 316–318. Ward, Lock, and Co., London.
text from p. 318, right column, last paragraph: "Monkeys have a remarkable fear of snakes, combined with an irresistible attraction. Even a dead snake exerts this influence, as was found by Mr. A.E. Brown in Philadelphia. A dead snake wrapped up in paper and put into a monkey house containing forty or fifty of various kinds, was carried off for fun by one of the larger specimens. But when the package became loose and the snake was seen, it was dropped at once; all the monkeys in house were attracted, and, displaying intolerable fear, formed a circle round the dreadful object. They remained in this position until a string attached to the snake was pulled, when they all fled precipitately with cries and screams; after a time they approached again, and took up similar positions, which they kept for hours. They showed no fear of a tortoise or a small dead alligator, but played with them quite freely. The dead snake, when shown to the mammals of other groups, was not noticed by them."
HUDSON, W. H. 1893. The bruised serpent. Macmillan's Magazine 67:451–457.
text from p. 451: "Darwin, on the slightest evidence, affirms that monkeys display an instinctive or inherited fear of snakes. There are many who would think any further inquiry into the matter superfluous; for, they would argue, if monkeys fear snakes in that way, then assuredly we, developed monkeys, must regard them with a feeling identical in character and origin... Fear of snakes is merely another example of historical memory, recalling a time when man, like his earliest ancestors the anthropoid apes, was sylvan and solitary; a mighty climber of trees, whose fingers were frequently bitten by birds' nesting colubers, and who was occasionally swallowed entire by colossal serpents of arboreal habits." *This article also mentions the "snake in a bag" experiment highlighted in the Universal Instructor or Self-Culture for All reference above.
BILBY, T. 1887. Simius- The Ape. In Young Folk's Natural History, with Numerous Illustrative Anecdotes, pp. 177–200. John W. Lovell Company, New York.
text from p. 182, "Illustrative Anecdotes": "We have already stated that both the Orang-outang and Chimpanze have, under the education of man, shown themselves grave, docile, and attached to those who were kind to them; but it may here be proper to remark, that in a domestic state at least, they entertain an unconquerable fear of serpents; and we are inclined to believe that this fear is innate, and no less absolute in their native forests, than when they are in captivity, notwithstanding that Labat says, "I have seen these monkeys playing their gambols upon those very branches on which the snakes were reposing, and jumping over them without receiving any injury, although the serpents of the country were naturally vindictive and always ready to bite whatever disturbed them". We should think the monkeys that thus amused themselves felt a consciousness of their own safety; since we have seen exhibitions of both these kinds of animals in the East Indies in the open air, where apes and serpents appeared to be reduced to a state of obedience, if we might judge from their movements (since we did not understand the language of their masters); but, although we have seen both kinds exercised thus, we never saw them exhibited together. One day a young Chimpanze was shown a large snake, for the purpose of ascertaining whether the fear said to be inherent in the genus to which he belongs, was really so or not, the creature never having before seen such a reptile. The instant he saw it, he shrunk up into a corner in the utmost alarm, which could not be mistaken; nor could anything induce him to go near the basket in which the snake lay, although fruit was placed on the lid, when it was shut down, to tempt him. Much, however, as he wished to obtain the fruit, he still kept aloof until the snake was altogether removed; when the apple being placed on a chair, he after a cautious examination, to satisfy himself that his enemy was gone, took the tempting bait to eat in safety. We believe this Chimpanze was under two years old when it died, and it was then, as we are assured cutting its teeth... "
HARTMANN, R. 1886. Anthropoid apes. The Literary World- Vol. 33, No. 844 (January 1, 1886):8–9.
text from page 8 (under "Apes in captivity"): "... She chased the mice which ran about her cage with deadly fury. She was much afraid of snakes, which is not usually the case with chimpanzees."
HARTMANN, R. 1886. Anthropoid Apes. D. Appleton and Company, New York. 326 pp.
text from p. 269, last paragraph: "There is, however, an account given by Broderip of a male chimpanzee, which was brought from the Gambia, and placed in the London Zoological Gardens in 1835... He displayed great terror when an anaconda was brought into the room in a basket, and did not dare to take an apple from off the closed lid of the basket; but as soon as the snake and its basket were removed, he ate the apple and became cheerful again..." [Broderip, W. J. 1835. Observations on the habits of a male chimpanzee. Proc. Zool. Soc. London. 1835:160–168.]

Although Orangutans were not vocal in the presence of snakes, they moved as far away from them as possible at London Zoo—"The Society has at present two examples—a young female which came two years ago as a very small baby, and a large, probably adult male. Both of these are extremely slow and deliberate in their movements, but as soon as they got sight of a snake and long before it was near them, they fled silently but with the utmost rapidity, climbing as far as possible with a ludicrous celerity." Mitchell (1929) saw that a young orang, removed from its mother (perhaps hand-reared?), behaved differently when presented with a large tame snake: "The orang was not in the least alarmed, but took the snake as a new and attractive toy, playing with it, allowing it to coil over him, and treating it with such friendly roughness that I had to remove it." Mitchell (1922) described Orangutan responses: "The instant recognition and betrayal of fear by special sounds and retreat, even in the case of a lethargic old Orang-utan, was so plain that I was disposed to treat them as instinctive, and even went the length of suggesting that the human dread of snakes might be an instinct from our ape-like ancestors." In 1917, a graphic exhibit developed by Mitchell again demonstrated that only some higher primates and a few birds showed fear of snakes.

In August 1872, Darwin finished the proofs for his book *The Expressions of the Emotions in Man and Animals*. In Chapter V, he compared the different responses by monkeys to a turtle and snake: "A living fresh-water turtle was placed at my request in the same compartment in the Zoological Gardens with many monkeys; and they showed unbounded astonishment, as well as some fear. This was displayed by their remaining motionless, staring intently with widely opened eyes, their eyebrows being often moved up and down. They occasionally raised themselves on their hind-legs to get a better view. They often retreated a few feet, and then turning their heads over one shoulder, again stared intently. It was curious to observe how much less afraid they were of the turtle than of a living snake which I had formerly placed in their compartment." When JBM was at the Dallas Zoo, general curator Jack Joy hid a newly hatched Ornate Box Turtle (*Terrapene ornata*) in his hand and presented it to an adult male Western Lowland Gorilla named Jimmy. When Jack opened his fist, Jimmy shrieked, jumped backwards, ran to the far end of the enclosure into an open doorway and peeked out at the turtle. Many years ago, Curator Ed Almandarz from Lincoln Park Zoo in Chicago told JBM that the famous male gorilla Bushman (known as Lord of Lincoln Park and the best known and most popular civic figure in Chicago) got out of his cage in October 1950, roamed through the ape house for three hours, and was tearing the primate building kitchen apart at the end. They tried everything to get it to return to its cage until Ed suggested sliding a live garter snake under the door. Bushman ran back to the cage and closed the door behind.

Fig. 1. Charles Darwin observed Orangutans over many years in the Regent's Park Zoological Gardens in London. He used Alfred Edmund Brehm's engravings from an earlier edition of Brehm's multi-volume work in *Descent of Man*. Illustration of Orangutan from *Brehms Thierleben. Allgemeine Kunde des Thierreichs* (1882–1884).

It is not unreasonable for Orangutans to be leery of snakes. In 1986, William Xanten (2014) from the Smithsonian National Zoological Park (NZP) went to the Sepilok Orangutan Rehabilitation facility in Sabah-Eastern Borneo, which for years maintained both orphaned and injured Orangutans (*Pongo pygameus*) for rehabilitation and eventual release. Two young orangs that appeared to be about two years of age had been kept in an outdoor, barred enclosure. Early one morning, a large Reticulated Python (*Python reticulatus*) approximately 12–15 ft (365–455 cm) in total length was discovered inside the cage with two distinct lumps about halfway down the body. Because the bars were close together, the snake was unable to escape after dinner.

Observations at the National Zoo

In the late morning of 18 June 2014, during a typical shifting routine in the Great Ape House, one of the NZP's Orangutans started acting strangely and refused to shift outside. A 41-year old hybrid Orangutan female named Lucy had climbed the tree in her indoor exhibit to use the upper chute to shift outside but she stopped at the shift door and refused to enter. She began to display piloerection and a unique vocalization that is used by her only in situations when she is extremely agitated. The keeper was unable to identify what was causing Lucy to display, being unable to see into the upper chute. Still displaying, Lucy climbed out of the tree to retrieve a plastic milk crate (an enrichment toy) from the floor of her enclosure and brought it back up into the tree; she used the crate to bang on the metal mesh of the upper chute. The Orangutans are not allowed to bring milk crates into the outdoor yard as they pose an escape hazard due to the glass barrier. These primates also have access to elevated cables to travel from one exhibit to another, called "O-Line," so it would not do to have them drop crates on visitors. The chute shift door is therefore kept partially closed so that the crate would not fit through the opening. It was only after several minutes of displaying—vocalizing and banging on the mesh with the milk crate—that Lucy calmed down enough to shift outside through the chute. Typically the Orangutans walk through the chute, but this day, Lucy held onto the mesh at the top of the chute, never allowing her feet to touch the floor. After Lucy was secured

outside keepers found a juvenile Black Ratsnake (approximately 18 inches [46 cm] in length) on the floor of the chute. Keepers were able to remove the snake and release it unharmed in the Park.

Two days later, another recent hatchling snake was discovered in the keeper section of the Great Ape House. ER presented the snake in front of the mesh screening to three Orangutans. Bonnie (37 years in age) stared intently at this ophidian and she was piloerect. Male Kyle (17 years) ran to the back of the enclosure and climbed to the top, as far as possible from the snake. Lucy stayed close but blew puffs of air toward the snake.

A similar incident had occurred several years earlier at the Think Tank exhibit at NZP. On 13 May 2012, female Orangutans Iris (then 25 years old) and Batang (then 15 years old) were displaying and reacting to something that was high up in their enclosure. A 12-inch (30 cm) juvenile Black Ratsnake could be seen sitting on the upper track of a hydraulic door, approximately 12 feet (3.6 m) above the floor. Both Orangutans were producing a belch vocalization that signified fear or displeasure. Each ape was gathering items from their enclosure such as browse, blankets, and toys, and throwing them at the snake. It was not until the Orangutans were shifted outside that they calmed down and keepers were able to remove the snake and release it into the Park.

Two years earlier, an adult ratsnake approximately five feet (1.2 m) long took up residence near the upper shift chute in the indoor gorilla enclosure but the keepers were unaware of its existence for two weeks. Female Kigali (18 years), male Kojo (11 years), and male Baraka (21 years) stood at the edge of the doorway and peered into the shift but were hesitant to move through for many minutes. Finally, they would sprint full-speed through the chute into the outside yard. They insisted on using another chute to return indoors at the end of the day. During this two-week interval, keepers discovered feces throughout the indoor cage but could not identify them until they found the snake in a mound of hay.

Fig. 2. John Edwards Holbrook published the multi-volume *North American Herpetology* beginning in 1836, covering all herps found east of the Mississippi River at that time. Shown is Black Ratsnake (*Elaphe obsoleta*).

Field Observations by NZP Primate Curator Meredith Bastian

My observations of wild Orangutans reacting to snakes: I have seen wild Bornean Orangutans (*Pongo pygmaeus wurmbii*) notice cobras, pitvipers, and on one occasion a Reticulated Python. I have seen several young Orangutans—still dependent on their mothers, so not yet weaned—attempting to play with sleeping pitvipers. On one occasion a somewhat older but still dependent female Orangutan came down fairly low at the site of a cobra, but her mother grabbed her back up the tree. The reaction of adult Orangutans is different—I have seen adult Orangutans notice snakes and immediately upon noticing the snake, the Orangutans moved further up the tree they were in, kiss-squeak at the snake, and move quickly onto the next tree. On one occasion I observed an Orangutan's reaction to a python that was crossing just over a trail that I was on. The particular Orangutan I was following was extremely well habituated to my presence and was low in the trees eating. As soon as she spotted the python, the Orangutan began kiss-squeaking, throwing branch "missiles," collected her infant, and moved quickly onto the next tree. I remember later that same day the female continuing to exhibit behavior that we normally see only in non-habituated animals,

PHOTO BY DENNIS DESMOND

Fig. 3. Entrance to Reptile Discovery Center at Smithsonian National Zoological Park. Eastern Ratsnakes (*Pantherophis alleghaniensis*) climb the brick façade and have been seen nearly 15 feet (5 m) above ground.

including persistent kiss-squeaking, throwing of branch missiles, and "snag crashing" (she knocked over a dead tree).

I have observed variable reactions of wild White-handed Gibbons (*Hylobates lar*) in Thailand and Agile Gibbons (*Hylobates agilis*) in Indonesia to snakes. While I have seen a juvenile White-handed Gibbon come down to a low branch and slap a sleeping pitviper, I have heard gibbons of both species give alarm calls at the presence of Reticulated Pythons and I remember once seeing a group of White-handed Gibbons alarm call at the presence of a cobra. Based on these observations I am not sure how accurate it is to assume that either gibbons or Orangutans are any less fearful of snakes than other taxa because they are arboreal.

Zoo with a Bunch of Snakes

Black Ratsnakes [also called Eastern Ratsnakes] (*Pantherophis alleghaniensis* = *Elaphe obsoleta*) are common throughout the Zoo (163 acres [66 ha]), which abuts Rock Creek and is an important urban park. This taxon seems to be increasing in numbers over the past ten years, based on the recollections of long-term employees. This may be, in part, a reflection of transient snakes that immigrate into the population through Rock Creek and stay because the prey base is increasing, due to an increase in animal exhibits with additional available food. In the Spring when snakes are most visible, there may be up to three visitor reports of sightings per day and this number is much larger than earlier years even though visitation is relatively constant, averaging over two million people annually. This snake is an excellent climber and sometimes scales considerable heights in animal enclosures to find prey, including collection animals on occasion (Sara Hallager, pers. comm.). In the large flight cage, an adult Mountain Bamboo Partridge (*Bambusicola fytchii*) was discovered inside a ratsnake and the bird weighed 350 g. Snakes have been found in tree tops over 40 feet (12 m) in this exhibit. Eggs sometimes disappear from nests and ratsnakes are the suspected culprits but have not been seen swallowing these packets of protein. A local chicken farmer brought in a living ratsnake to the Zoo with a large swelling at mid-body. He used two golf balls as dummy eggs to increase production and the snake had swallowed one of the spheres. The indentations on the ball could be seen on the radiograph and the ball was surgically removed. A year later, the second ball was found by the farmer in another snake, which understandably was severely emaciated and expired shortly thereafter. A ratsnake swallowed a newly-hatched American Flamingo (*Phoenicopterus ruber*) standing 8 in. (20 cm) and weighing ca. 120 g. Kori Bustards (*Ardeoyis kori*) are afraid of snakes and run from them. Native birds and small mammals are attracted to foods offered to animals in the collection and snakes may intercept them. JBM watched an adult American Robin (*Turdus migratorius*) spar with a ratsnake ca. 24 inches (61 cm) long for well over an hour—a series of attacks and counter-attacks. The snake was striking continually at the bird to grab it in order to throw coils around it; the bird countered with wings outstretched and rapid thrusts with beak attacks, directed mainly at the snake's head after the strike. Neither combatant retreated—the conflict ended in a draw when the bird took flight. An adult ratsnake was climbing up a tree toward a Northern Flicker (*Colaptes auratus*) nest approximately 15 feet (5 m) above ground. As the snake ascended, one of the parents tried to dislodge it by vigorously pecking its body but was unsuccessful. The snake crawled into the nesting cavity and consumed three fledglings. In 2010, a hatchling ratsnake, emaciated and dehydrated, was trying to swallow a dead adult vole killed on the zoo road by a vehicle, but to no avail as it was far too large. A keeper separated the two animals, caught the snake, and put it into a jar. A newborn laboratory mouse was offered and quickly swallowed. An hour later, the mouse was back in the jar. The rodent was again presented and swallowed by the snake. Another hour passed and the mouse was back again. The third time, the keeper watched and the mouse was swallowed but emerged from a major gash on the snake's venter behind the head. Upon closer examination, a scab was found across the dorsum, clearly made with an attacking bird's beak. This snake was euthanized.

In the Fall, ratsnakes may be found in buildings, no doubt searching for hibernation sites. Six juveniles have been found throughout the reptile building. One climbed up the slippery bronze rod door closing mechanism to a height of 5 ft (1.5 m); it entered the building through a small gap under the door. Another young adult crawled through four mouse snap traps in the basement feed room—it did not survive. Adults and juveniles have been found in the Commissary, Amazonia exhibit, Bird House, Elephant House, Invertebrates, and Small Mammal House.

How do ratsnakes climb buildings? JBM once found a young adult snake approximately four feet long (1.2 m) on the flat roof of the two-story reptile building (description by Murphy and Xanten 2007), a distance of approximately 20 ft (6 m) from the ground. There were low trees nearby with overhanging branches—there are two possible explanations: either a raptor may have carried the snake to the roof (there were no visible injuries) or the snake may have climbed these trees at first and continued crawling upward on the brick façade to the roof. Although Robin Saunders (pers. comm.) saw a Red-Tailed Hawk (*Buteo jamaicensis*) snatch a large adult ratsnake in the nearby Zoo parking lot, the latter explanation seems more likely. These birds are often seen hunting in the Zoo and surrounding neighborhoods and may be an important predator upon ratsnakes (see Fitch 1963). Ratsnakes have climbed the reptile building (built in 1931 with large spaces [5/8-inch high or more (15 mm), 1/3-inch deep (8.0 mm)] between bricks filled with mortar) in a stepwise fashion by following these spaces between the bricks and wedging their bodies in these places to secure stability. A snake begins by crawling vertically on the side of a brick until the top is reached, then turning horizontally along the top of the brick until reaching the next vertical space. A young juvenile and three-foot adult (1 m) were found attached to the reptile building nearly 15 feet (5 m) above ground in a zig-zag configuration; there were no trees nearby (Fig. 3).

Carl Gans (1974) discussed lateral force application in North American *Elaphe*. "Progression proceeds by a combination of undulation and concertina, and it is curious to see these animals apply themselves to a [tree] trunk and climb it with their body thrown into thirty or more short-radius bends. Such species derive an obvious advantage by being able to apply these forces as close to the surface as possible; many of the discontinuities against which they stem do not project far. These snakes (no other tetrapod shows this adaptation) have changed their cross section so that the widest point lies at the ventral surface. The wide ventral scutes show a sharp vertical bend on each side, and these lateral keels serve for force application."

How do ratsnakes return to the ground? Harvey Lillywhite (2014) shows a picture of a Yellow Ratsnake (*Pantherophis obsoletus*) clinging to a pine tree and pointing downward— "It is not clear whether snakes are able to proficiently move downward on such a tree trunk, or whether they simply fall (purposely) to the ground."

Summary

These ophidians are occasionally found in indoor primate enclosures. These accounts are not the first times that the zoo's Orangutans have reacted to snakes in their enclosures. Though it is unclear whether the Orangutans intend to kill the snakes or simply move them, the Orangutan's retrieval and use of objects (e.g., pieces of browse, enrichment items) to aid them in each of these interactions with snakes is impressive.

As an aside, studying a population of wild snakes in a zoo setting can be informative, especially since visitors can assist as snake spotters to build a larger database. David Roberts and the herpetological staff began a 13-year mark and recapture study of Texas Ratsnakes (*Pantherophis obsoletus lindheimeri*) at Dallas Zoo (Roberts and Mitchell 1998). Ruston Hartdegen (2004) examined the population dynamics and activity patterns of these snakes throughout the year. A total of 206 snakes were collected during the study period over the course of 395 total capture events. He reported on overall population size distribution, examined the growth rate of recaptured snakes, and evaluated the effects of parameter manipulation on resulting growth data. Such variations in data collection parameters can significantly alter the interpretation of growth data for the species in question.

Acknowledgments.—This contribution is dedicated to primatologists Lisa Stevens and the late Devra Kleiman, who spent their professional careers in service to NZP. Lauren Augustine, Ben Beck, Judith Block, Lee Jackson, and Steve Sarro reviewed an early draft. Thanks are due to Matt Evans, Sara Hallager, Robin Saunders, and especially Robert Mendyk.

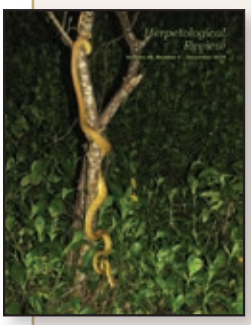
Mountain Chicken (*Leptodactylus fallax*),
Laura Hampton — Available at both A3 (11.7″ x 16.5″) and A4 (8.3″ x 11.7″) paper sizes

The critically endangered Mountain Chicken (*Leptodactylus fallax*), or "Giant Ditch Frog," is a large (up to 210 mm SVL), robust anuran native to the Caribbean islands of Dominica and Montserrat. With an average lifespan of 12 years, it reaches breeding maturity at roughly three years of age. Unlike most anurans, which breed in water, this frog deposits its eggs within a terrestrial foam nest in underground burrows about 50 cm deep. This occurs in April during heavy seasonal rainfall. Once the eggs have developed, the adult female will lay many unfertilized eggs to feed her brood. The female will then guard them until they are fully developed and they leave the safety of the burrow.

Unfortunately, like many amphibian species, the Mountain Chicken frog is suffering declines from chytrid fungus. There are other factors contributing to its decline including natural catastrophic events, such as volcano eruptions, as well as mass consumption for food by humans (this frog is the national dish of Dominica) and habitat loss for agricultural practices. In addition, this species has a low reproductive rate and reaches sexual maturity later than many frog species. Due to these impacts, the Mountain Chicken is estimated to have declined by 80% within the past ten years.

There are now several organizations working to save this species. Although hunting is now banned and there are projects in place to help increase populations, there are still only two breeding projects outside Dominica. One of these is at London Zoo, with a successful captive breeding program; the other is a private collector in the United States working with a small collection of frogs.



Laura Hampton is 24 years old and has been drawing and painting her entire life, typically working with nature-based subject matter.

Her current personal preference for animal-based pieces includes a mix of different media. The Mountain Chicken Frog piece presented here began with a water color pencil base, and then colored pencil was used for detail. Finally, acrylics were used to add stronger colors and highlights and shading for a bold, eye-catching appearance.

Laura produced this Mountain Chicken Frog piece to help raise money and awareness for the conservation of the species as part of an ongoing project coordinated by the Dominican Mountain Chicken Frog Project. Fifty percent of profits from sales of prints will be donated to that project.

Laura offers commission work, from pet portraits to book illustrations, and has current work for sale, including Mountain Chicken Frog prints, at www.facebook.com/lauraaprilart. She can also be contacted via laura.april.h@gmail.com for more information.

ABOUT OUR COVER: *Corallus grenadensis*

Corallus grenadensis, endemic to the Grenada Bank (Grenada + the Grenadine Islands), is one of two species of *Corallus* that occur in the West Indies (*C. cookii* on St. Vincent is the other). Although the impact of humans on pre-Columbian environments should not be underestimated, it was the arrival of European colonizers on Grenada that led to large-scale deforestation for sugarcane production in the 18th century. Except on the steepest portions of the island, virtually all original forest was cleared and this must have had a profound impact on the distribution and ecology of *C. grenadensis*. Today, Grenada is a mosaic of land cleared for agriculture, small towns and villages, and wooded areas; this patchwork landscape is obvious when flying over the island. Nevertheless, *Corallus grenadensis* is widespread on Grenada from sea level to about 530 m, and it occurs in a wide range of habitats, including xeric scrub, mangroves, orchard trees (e.g., mango, cacao, breadfruit), and lush forests. Finding *C. grenadensis* foraging in proximity to human activity (residential gardens, the grounds of upscale hotels) is not unusual, and it will enter homes and outbuildings and cross urban roads on power lines. In the Grenadines chain, it occurs on at least ten islands, ranging in area from 0.46 km^2 (Petit St. Vincent) to 32 km^2 (Carriacou). These small islands have no original forests (all were cleared for sugarcane and cotton), yet *C. grenadensis* can be abundant in some areas.

Like its close relative *C. hortulanus* on the South American mainland, *C. grenadensis* exhibits a spectacular variety of color patterns. In open, sun-drenched habitats, boas tend to have a yellowish ground color and often lack any discernible pattern. At sites above ~400 m, where temperatures are cooler and heavy cloud cover and rainfall are regular events, boas are very dark brown (verging on black) with a pattern of fine, white, lace-like markings. At moderate elevations, boa ground color may be any of many shades of yellow, orange, red, brown, or gray, with or without a conspicuous pattern.

The diet of *C. grenadensis* undergoes an ontogenetic shift in vertebrate prey from ectotherms to endotherms. Neonates (~300–380 mm SVL) to snakes of about 700–800 mm SVL are nocturnally active foragers that prey almost exclusively on sleeping or resting *Anolis* lizards. Boas in these age/size classes display amazing stealth when approaching a sleeping anole. In two feeding episodes video-taped in the field, boas moved at the rates of 0.8 cm/minute and 1.4 cm/minute, thereby requiring 24 and 14 minutes, respectively, to cover the last 20 cm (Yorks et al. 2003. Studies on the Neotropical Fauna & Environment 38:167–172). Similar behavior has been observed in *C. cookii* and *C. hortulanus*. Large (>1000 mm SVL) *C. grenadensis* become ambush foragers that prey primarily on nocturnally active rodents and, rarely, on birds or Mouse Opossums (*Marmosa robinsoni*).

Over the past 500+ years, *Corallus grenadensis* has had to adapt to new habitats (often dominated by introduced tree species), new prey species (the introduced rodents *Mus* and *Rattus*), and introduced predators (mongooses, opossums). Avoiding a conspicuous human-presence on Grenada is virtually impossible; that this species is as widespread and locally abundant as it is while in close proximity to human activity is testimony to its adaptability.

The snake on the cover is an adult female *C. grenadensis* (1050 mm SVL) that was photographed at a site in central Grenada. It has assumed a posture often seen in adult *Corallus* of several species (Henderson 2015. Natural History of Neotropical Treeboas [genus *Corallus*]. Chimaira). With head angled downward and about 30 cm from the ground, boas wait for passing prey. On Grenada, that is usually *Rattus rattus*. The boa was photographed with a Canon PowerShot SX500IS with 4.4–129 zoom lens and built-in flash. The photographer is **Robert W. Henderson**, Curator of Herpetology Emeritus at the Milwaukee Public Museum. Henderson has been working with West Indian *Corallus* for about 25 years, with the primary focus on *C. grenadensis*. Additional *Corallus*-directed fieldwork has taken place on St. Vincent and on Trinidad (with *C. ruschenbergerii*). His fieldwork with *Corallus* is ongoing.

SSAR BUSINESS

2014 Annual Meeting, Chattanooga, Tennessee

The 57th Annual Meeting of SSAR took place from 30 July to 3 August 2014 at the Chattanooga Convention Center in Chattanooga, Tennessee (Fig. 1). This was the first shortened (four-day) JMIH. Organizing societies this year were Society for the Study of Amphibians and Reptiles (in conjunction with the International Society for the History and Bibliography of Herpetology), American Elasmobranch Society (celebrating its 30th annual meeting), American Society of Ichthyologists and Herpetologists (celebrating its 94th annual meeting), and The Herpetologists' League (celebrating its 72nd annual meeting). The local hosts were Anna George (Chair), Josh Ennen, Bernie Kuhajda, and David Neely (all from Tennessee Aquarium Conservation Institute), and Eric O'Neill (University of Tennessee at Chattanooga). They were assisted by the following volunteers: Sarah Hazzard, Kathlina Alford, Heather Boud, Louise McCallie, Lindsay White, and Shawna Mitchell. We thank them, and the KState folks, for all for their hard work and another enjoyable JMIH. Chattanooga was a great place for a meeting. The weather was great, the nearby hills and river were beautiful, the Convention Center was well-laid out, and some of the local restaurants were worth revisiting 2 or 3 times (who'd have though grits with goat cheese was so delicious?).

PHOTO BY M. PREEST

FIG. 1. View of the Chattanooga Convention Center.

Approximately 950 herpetologists and ichthyologists attended the meeting. This number includes 459 students and 349 members of SSAR. SSAR was pleased to sponsor the attendance of two pre-baccalaureate students (Alli Metler and John Erickson) and their chaperones. Alli and John participated in the SSAR Mentor Program (along with 15 graduate students and their mentors). Thanks to Kris Kaiser and Andrew Durso for doing the lion's share of the work again to make this program possible. The meeting included 69 oral sessions, 238 poster presentations, and three symposia. SSAR sponsored a symposium entitled "Infrared Imaging: Cellular/Molecular Mechanisms, Behavioral Biology and Ecology of Pit Vipers, Pythons, and Boas." Thanks to Michael Grace for organizing this afternoon symposium that included seven presentations (Fig. 2). Symposia sponsored by ASIH and HL were "Bridging the Gaps: The Remarkable Career of Gordon M. Burghardt in the Study of Herpetofaunal Behavior" and "Reproductive Biology and Phylogeny of Lizard and Tuatara," respectively.

Social and Professional Events

Following the usual pre-conference day of Board and Executive Committee meetings, the JMIH began officially with the Plenary Session on July 31st. Local Host Committee Chair, Anna George (Director and Chief Research Scientist, Tennessee Aquarium) welcomed us to Chattanooga and oriented us to the layout of the city. She mentioned some of the local attractions—the Creative Discovery Museum, an outdoor climbing gym near the Aquarium, the River Gorge Explorer along the Tennessee River, the Chattanooga Zoo, nearby whitewater rafting, Chicamauga National Park, and Ruby Falls (Fig. 3). Some of these are accessible via a free downtown shuttle that many of us took advantage of during the week.

FIG. 4. David Blackburn, President's Travelogue speaker, in front of the poster advertising his talk.

Various awards were then presented. The ASIH Robert H. Gibbs Award was given to Naericio Menezes and the Robert K. Johnson Award for Excellence in Service to ASIH was presented to Larry Page. The Henry S. Fitch Award for Excellence in Herpetology was presented *in absentia* to Marvalee Wake by Darrel Frost. Darrel nicely summarized Marvalee's amazing career and particularly noted her "signature virtue" as a role model, especially to women, in a traditionally male-dominated field. He was quite correct to say that she has, and will continue to, inspire female herpetologists for decades.

Craig Guyer announced Alan Richmond (UMass, Amherst) as the winner of the 2014 SSAR/HL/ASIH Meritorious Teaching Award in Herpetology. Craig noted that Al has taught herpetology for 20 years, bringing an enthusiasm to the classroom that is reflected in his infectious teaching style and his willingness to main diverse live animals to serve as teaching aids. What was particularly notable was the fact that he has shaped the careers of people well outside the bounds of academic herpetology.

The first Meritorious Teaching Award in Ichthyology was given to Gene Helfman who admitted that he would only use the award to buy more fish t-shirts and thus donated $500 to the ASIH Student Travel Fund. The Joseph Nelson Award for Lifetime Achievement in Ichthyology was presented to Bruce Collette.

Jeremy Monroe (Filmmaker, Aquatic Biologist, and Director, Freshwaters Illustrated) was then introduced as the JMIH Plenary Keynote Speaker. What a treat! Jeremy admitted that he was an "obsessed fishing kid growing up" and read all the fishing magazines and watched the TV shows. However, towards the end of his time in graduate school, he started to question what the popular image of fishing was doing and how it has affected how we perceive freshwater biodiversity. He showed us some of the truly stunning short films he been involved with, particularly in the southeastern US. Jeremy said that the mission of Freshwaters Illustrated is to "educate diverse public audiences about the life, study, and conservation of freshwater ecosystems…and to provide illustrative resources…to scientists, educators, and media specialists."

After a break, ASIH Past President William Matthews gave a presentation on "Synthesizing your Career Data: A Challenge for Old Folks and Suggestions for Young Folks." This was followed by a presentation by Chris Lowe, the AES plenary speaker ("Is 'The-Sky-is Falling' Science Really the Only Solution for Elasmobranch Conservation"), who suggested that we need to start thinking differently in terms of how we "message" our science and warned that if we constantly cry wolf, eventually the public and media will stop listening.

The plenary session was wrapped up by J. Whitfield Gibbons (HL Distinguished Herpetologist). The title of Whit's talk (although not one he made up) was "What We Didn't Know in 1964: Fifty Years of Herpetology." Whit's first piece of advice was to "relax before a talk—no matter how many you give, one will be your best and one will be your worst!" He also said "if you're going to he a herpetologist, enjoy what you're doing. If it's not fun, you shouldn't be doing it!" More seriously, he noted that the world's herpetofauna is "under siege" and that people must know what they have, to know that they could lose it. He spoke about the role of public education and the realization of its importance in conservation efforts. For part of his talk, Whit focused on the work he and his many colleagues carried out at Ellenton Bay at SREL (Savannah River Ecology Lab in Georgia) and the differences in productivity between seasonal and permanent wetlands. He also spoke about research on cottonmouth behavior that questioned the stereotype of these snakes as aggressive.

Following the Plenary Session, we gathered in the main corridor of the Convention Center for the group photo.

David Blackburn (California Academy of Sciences) gave the 2014 SSAR President's Travelogue ("Adventures with African Amphibians") on the evening of July 30th (Fig. 4). David described himself as an "unlikely" herpetologist and spoke of the many projects he has been involved with over the past 12 years, most of them in Africa, particularly Cameroon (but also Angola, Burundi, Tanzania, Uganda, Ethiopia, Egypt, Libya, Nigeria, etc.). He said that this is the time to go to Africa and get involved with biodiversity and conservation studies. Although getting places is not always easy, you are rewarded with amazing biodiversity. David spoke about phenotypic diversity and incredible variation in color patterns in frogs, and even variation in the way they smell. He noted the decline in frog abundance in some areas and the recent appearance of chytrid. He finished by describing some of the efforts of the African Amphibian Working Group in training local herpetologists, including students, in tissue collection.

Over 100 students and 30 professionals attended the SSAR/HL Student Reception held in a rotunda in the Convention Center in the late afternoon on July 31st. SSAR and HL thank the donors of door prizes. The Student Reception was followed by the JMIH Opening Reception at the Tennessee Aquarium. The food was great (many of us ate outside overlooking the Tennessee River) and the exhibits, split between two large buildings, were spectacular. It's not surprising that the aquarium has been rated "Best Aquarium in America" for three consecutive years!

The SSAR/HL live auction was held on August 3rd. We raised just over $6800. After all bills are paid, proceeds will be split 50-50 with HL. Auctioneers Sean Graham, Travis Hagey, and Sara Ruane were assisted by Krista Mougey, Elyse Freitas, Catriona Hendry, Rachel Skinner, and Arianna Kuhn; Figs. 5, 6, and 7). Ann Paterson, Kirsten Nicholson, Meredith Mahoney, Greg Watkins-Colwell, and Samantha Kahl ably handled the logistics and financial side of the evening. Several one-of-a-kind items went up for auction, including several t-shirts made just for the event. These included herp-humor, sometimes directed at specific researchers or projects, but also focusing on interesting anatomical features of some of our favorite species. A t-shirt featuring illustrations of a variety of snake hemipenes sold for several hundred dollars.

Mike Jorgensen (co-Chair Student Travel Awards Committee) conducted the random draw of names for this year's winners of travel awards. Vinny Farallo (co-Chair Student Travel Awards Committee) attended the 2014 JMIH and was able to oversee to silent auction. The auction items were set up in the lobby of the conference center. Once again, the ten recipients of the $400 SSAR Student Travel Awards took turns to work the silent auction table for 2–3 h throughout the course of the meetings. The Silent Auction raised just under $600.

Board and Business Meeting Summaries

SSAR Board Meeting

Society President Bob Aldridge called the Board Meeting to order at 0758 h on 30 July 2014 in the Chattanooga Convention Center, Chattanooga, Tennessee. In attendance were the following members of the Board of Directors, Editors, and Committee Chairs: Bob Aldridge (President), Paul Bartelt (co-Editor *JHerp.*), Aaron Bauer (President-Elect; Editor, *Facsimile Reprints in Herpetology*), Rafe Brown (Chair, Seibert Award Committee; Chair,

Local Meeting Committee, 2015), Alison Cree (Board Member, non-US 2016), Brian Crother (Chair, Standard English and Scientific Names Committee), Tiffany Doan (Board Member, Reg. 2014; co-Editor *JHerp.*), Richard Durtsche (Coordinator, Symposium Committee), Vincent Farallo (co-chair, Student Travel Award Committee), Marina Gerson (co-Chair Membership Committee), Ann Paterson (Treasurer; co-Chair, Membership Committee), Marion Preest (Secretary), Al Savitzky (SSAR Representative to AIBS and BioOne), Greg Watkins-Colwell (Board Member, Reg, 2016; Organizer, SSAR/HL Live Auction), and Dawn Wilson (Chair, Student Participation Committee). Additional society members present included Robin Andrews, David Auth, Jim Christensen, Darrel Frost, Rich Glor, Roy McDiarmid, Henry Mushinsky, Erin Muths, Kirsten Nicholson, Todd Pierson, and Robert Powell.

Introductions were made and minutes of the 2013 Board of Directors Meeting (Albuquerque, New Mexico) were approved.

Officers' Reports

President Bob Aldridge reported that he appointed Craig Guyer, Auburn University, as Chair of the Herpetological Education Committee and appointed Tiffany Doan and Paul Bartelt as Co-Editors of *JHerp*. He sent thank you letters to 29 associate editors of *JHerp.*, and signed a letter that the SSAR Conservation Committee wrote to Andy Gluesenkamp, Texas Parks and Wildlife Department, encouraging them to adopt amendment §65.328, banning the use of noxious and toxic substances to collect nongame wildlife (e.g., rattlesnakes). Additionally, he wrote a letter to over 700 members of SSAR who did not renew their membership in 2014. At the request of Dr. Hidetoshi Ota, managing editor of *Current Herpetology*, he wrote a letter to Thomson-Reuters recommending that *Current Herpetology* be included in the index of Thomson-Reuters database. The President signed congratulatory letters to: David Friend, Chair, California Turtle and Tortoise Club on the occasion of its 50th Anniversary; East Texas Herpetological Society on the occasion of its 25th Anniversary; Scott Keogh, Australian Society of Herpetologists on the occasion of its 50th Anniversary; Österreichische Gesellschaft für Herpetologie meiner Gesellschaft on the occasion of its 25th Anniversary; and Deutsche Gesellschaft für Herpetologie und Terrarienkunde Gesellschaft on the occasion of its 50th Anniversary.

President Aldridge met with the JMIH Meeting Management and Planning Committee in Chattanooga, TN, in April 2014. Times and places for the business meetings, sessions, etc., were arranged. All of the rooms at the Chattanooga Convention Center and various hotels were visited.

President Aldridge invited David C. Blackburn, Assistant Curator of Herpetology, California Academy of Sciences, to give the 2014 SSAR President's Travelogue at the JMIH meeting in Chattanooga, TN.

Treasurer Ann Paterson reported that SSAR had a mixed financial year during 2013. Most expenses were close to predictions and our investments did well. However, membership and publications income is down substantially. In part, this reflects lower membership numbers and reduced sales. However, it may also reflect timing of membership deposits to some extent. We overspent our budget this year by $38,092. This closely matches the amount by which we underspent our budget last year ($42,516).

After a year as treasurer, Ann has developed some proposals for things that she thinks will help SSAR manage its finances.

1. We have adopted a new credit card system through Bank of America to increase security of credit card processing and to increase our protection from liability.

2. Ann has developed (based on templates through our PCI compliance provider, Trustwave) a security policy for SSAR. This policy is on file with the secretary. In addition to the general security policy, Ann has arranged with Bob Aldridge to provide him with an updated MDISC of our financial records each year so that more than one person has these records. The records will include financial correspondence, bank statements, invoices, and QuickBookPro files. By having these records on file with the president, rather than just with the treasurer, we will facilitate future transitions between treasurers and ensure that someone can rapidly access important information even if the treasurer is not available for some reason. Additionally, this provides more oversight and transparency for the treasurer position

3. Ann has consulted with our accountant to obtain recommendations for how we can complete our taxes earlier in the year. Having our accountant review our books and complete our taxes is extremely helpful in presenting accurate, up-to-date information at the board meeting.

4. Ann has consulted with our Fidelity advisor twice over the past year about our investments. SSAR now has a substantial investment portfolio that needs to be managed carefully. Either the treasurer or some group of individuals needs to develop an investment strategy to present to the board so that we can decide on an appropriate investment approach, without excessive risk or lack of growth. Treasurer Paterson has obtained information and quotes from several investment managers and thinks that we should consider having an investment manager handle our investments. This would provide transparency and consistency in our investment strategy, even when treasurers are replaced.

The approved 2013 budget was balanced and despite some expenses going over budget, most of our expenses were under budget. We received a profit rather than a loss on the 2013 JMIH meeting, which is a positive development.

Overall, expenses and income were relatively close to expectations except for the substantial drop in membership dues this year. In 2012, total membership dues were $206,532. The board approved an estimate of $200,000 for the 2013 membership dues. While we do not yet have a definite final amount for the 2013 membership dues as Breck Bartholomew and John Psaltos work to determine the cause of some discrepancies in the calculations, the total will be close to $100,000. Although this may be partially explained by timing, it is still a concern and has caused us to run over budget in 2013.

The Society's investments continued to increase during 2013, in keeping with the trends in the global market. The total market value as of 31 December 2013 was $718,539. As of June 2014, we had increased further to $749,585.73. This is an increase of $83,563.73 in one year. Examination of the performance of our funds shows that their percent yields have increased over 2013, and have been increasing over the course of 2014.

Secretary Marion Preest provided Officers, Editors, and Committee Chairs with minutes of the 2013 Board Meeting, summarized the 2013 Annual Meeting for publication in *Herp. Review*, and regularly updated the SSAR letterhead to reflect changes in personnel. She informed the Editors of *Journal of Herpetology* and *Herp. Review* of these changes and provided various updates for Raul Diaz (webmaster). Marion also wrote letters to student winners of various awards and prepared announcements for publication in *Herp. Review*. She compiled the 2014 Annual

Report, prepared agendas for the Board and Business Meetings for the 2014 JMIH, and was again involved in organizing a reception for student members of SSAR and HL to be held at the Annual Meeting. Marion called for votes from the Board on various issues (e.g., proposals regarding use of funds for the Roger Conant GIH Awards and the Student Travel Awards, symposium proposals, etc.), circulated documents that needed to be signed by members of the Board (e.g., Conflict of Interest), confirmed eligibility for participation in various student activities, and dealt with many emails and phone calls from SSAR members and the general public.

Breck Barthlomew (Publications Secretary) reported that sales for the first five months of 2014 have been lower than during any other period since late 2001. He has noticed a similar trend with his bookstore, so doesn't think this is unique to SSAR. Sales during 2013 look quite robust, but these are due primarily to two factors: 1) Sales of *Erpétologie Générale* (which have now dropped off significantly). 2) A clearance sale on many older books, most of which were then remaindered in 2013. During 2014, Breck intends to have another clearance sale and offer some more titles to remainder dealers.

Breck does not think that book sales will ever pick up to where they were historically. Times have changed and few people maintain personal libraries any longer. As an example, the forthcoming *Contributions to the History of Herpetology Volume 1, Revised* has been advertised in an e-mail list, on Facebook, and in *Herpetological Review*. As of 27 June 2014, Breck has received orders for 13 copies.

What does this mean for SSAR? In Breck's opinion, we need to completely rethink our publications series and approach. Breck acknowledges that the publications series have always had room to publish books that were unlikely to make the society money simply because there was a need for the information to become readily available. Without being able to sell an adequate number of copies, the society needs to either move to a very small print run for most titles with the option of printing more as needed—this has been done with some circulars—or perhaps we need to move to an eBook model, or even publish books online in an open access model.

In recent years, SSAR has also received several donations of libraries. In the past these have made a considerable amount of money. However, like our publication sales, it is becoming increasingly difficult to liquidate these libraries—particularly the journals and separates in these collections. Breck is stepping up an effort to get these collections listed and put on the SSARbooks.com website. He will attempt to sell the items through other avenues as well, but some that he thought might be viable have been too risky to try—auction houses tend to expect books to sell at a fraction of their retail value.

Breck's goals for the remainder of 2014 and 2015 are to continue to reduce the overall SSAR inventory of books through sales and remaindering older titles. He intends to list many of the donated books, reprints, and other items on the SSARbooks.com website, and to consolidate the overall SSAR inventory to reduce storage costs.

George Pisani reported that he again filed SSAR's annual corporate report with the Office of the Kansas Secretary of State.

Editors' Reports

Co-Editors of *Catalogue of American Amphibians and Reptiles*, Chris Bell and Travis LaDuc report that the first three new *CAAR* accounts under their watch as co-editors have been published and are available via open access at www.SSARCAAR.com. These accounts are *Graptemys gibbonsi* (#901, Lovich and Ennen), *Anolis smaragdinus* (#902, Les and Powell), and *Cubophis vudii* (#903, Powell). The on-line, PDF format has eased previous concerns on manuscript length and allows the potential for numerous photos. Six additional accounts are currently in various stages of review. Chris and Travis continue to field inquiries for new accounts. They encourage potential authors to not only look at those species for which no accounts exist, but also at many of the published accounts; over half of all existing accounts are 25+ years old and an amazing amount of literature has been published over that same time period.

Chris and Travis assumed all of the editorial responsibilities in an effort to maintain the high standards of the series, particularly in the formatting and completeness of the literature citations, personally vetting every citation just like Andy Price and Bob Powell did before them. In order to streamline this vetting process, they have invested a tremendous amount of time over this past year into collecting, organizing, and indexing large amounts of published, but not-yet-indexed herpetological material. As a result, they have been able to add dozens of citations to accounts under review, further solidifying the relevance of these accounts as the authoritative reference for a given taxon. Bob Powell vouched for the fact that Travis and Chris have been very thorough and have both invested a huge amount of time in this series.

Chris and Travis thank the authors of the first three accounts for their patience as they learned the ropes of desktop publishing. They especially thank Bob Powell, Breck Bartholomew, and Ruthe Smith for their help in navigating through the logistics of editing this series.

Kraig Adler, Editor of *Contributions to the History of Herpetology*, reported that volme 1 (revised and expanded) was distributed to delegates at the first WCH in Canterbury, September 1989, but has been out of print since 2000. With volumes 2 and 3 now available, a reprint will allow purchasers to have a complete set. The reprint, however, will be heavily annotated and also include six portraits missing in volumes 1–3 and corrections to all three volumes. There are also 96 plates (mostly in color) added, with substantial captions. This book is scheduled for publication in August 2014.

Projects beyond 2014 include "Herpetology at the University of Kansas," by William E. Duellman, which will be a detailed history of one of the most distinguished herpetological research and graduate education programs. It includes Henry Fitch's long-term program at the Natural History Reservation, biographies of all herpetological graduates of the KU program, and summaries of major expeditions, meetings, and other activities. This book will be issued in 2015 in the run-up to SSAR's meeting at KU later that year. Also in the pipeline are *A Guide to the Snakes of the Philippines* by Rafe Brown, Alan Leviton, Maren Gaulke, and Arvin Diesmos (to be issued 2016), *Salamanders of Japan* by Ikio Sato (for which a grant for $55,000 was obtained from the Seidell Program at Smithsonian to cover the translation by Richard Goris), *Field Guide to Amphibians and Reptiles of the West Indies* by S. Blair Hedges, *and Lizards of Southern Africa* edited by William R. Branch and Aaron Bauer.

Aaron Bauer (Editor, *Facsimile Reprints in Herpetology*) notes that activity this year has been associated with progress on the production of *The Collected Herpetological Works of Giorgio Jan* with an introduction, annotated bibliography, and extensive systematic comments by Roy McDiarmid and Jay Savage. The

work includes a reprint of a near full-sized facsimile of the *Iconographie Generale des Ophidiens* and Jan's other herpetological 500+ manuscript pages of new material by McDiarmid and Savage. Scanning of the original works of Jan is underway and the major task of scanning the *Iconographie* will be undertaken by a commercial firm in San Francisco identified by the California Academy of Sciences, which has kindly provided their immaculate copy for reproduction and has committed to partially funding the scanning costs. In addition, remaining costs of scanning have been provided by Ronald Javitch and Jay Savage. Re-estimation of costs for production of this volume have increased by several thousand dollars as the Academy's original offer to cover these costs had to be revised. On the other hand, changes in layout and the removal of nearly entirely redundant Jan papers (differing only in pagination) have reduced printing estimates to approximately $18,000 (from an original $30,000) as the entire work can be produced in a single volume of slightly more than 1000 pages at a trim size of 9 x 12 inches. It is still anticipated that this work will appear in 2014, although probably in late Fall.

In 2015, Aaron anticipates the publication of *The Collected Herpetological Works of J. V. Barboza du Bocage (1823–1907)* with an introduction, annotated bibliography, and data on types by Luis Ceríaco. The facsimile will include approximately 150 manuscript pages of new material dealing with Bocage's life and works, his complete bibliography, and short accounts for each of the 104 species of amphibians and reptiles he described. Ceríaco anticipates an interest by the Portuguese Academy of Sciences in supporting the work through co-publishing, which may cover approximately $6,000 of the production costs.

Cantor's *Zoology of Chusan* (1842) and his *General Features of Chusan* (1842) together comprising 70 text pages and 11 leaves of plates, an early treatment of the herpetofauna and other natural history of Zhoushan, Zeijiang Province, China will be prepared as a facsimile give-away for the next World Congress of Herpetology, to be held in nearby Hangzhou, China in 2016.

John Moriarty (Editor, *Herpetological Circulars*) reported that *Herpetological Circulars* 41 (*A Guide to Tissue Collection, Preservation, and Management for Reptiles and Amphibians*) was published Spring, 2014. John is working on revising *HC* 42 – *Herpetological Collecting and Collections Management*.

Editor of *Herpetological Conservation*, Joe Mitchell, reported that he still has not received inquiries for a new publication in this series despite an advertisement in *Herp. Review* 45. Joe proposes placing an advertisement in *Herp. Review* again. If there are still no responses he suggests conducting a review of herp-related conservation publications to see if the book series fills a valuable niche. If it does not, then Joe suggests that we cease publication of the series. If it does, then consider another *Herp Conservation* book with Joe perhaps as a co-editor that would generate enough sales to be profitable to SSAR, e.g., a book focusing on successes and failures in herp conservation that includes critical evaluations of examples in several countries with the explicit goal of elucidating what works or not and why or why not, includes a review of e.g., selected Endangered Species Act (US) and PARC projects, has a clear standard to measure success, and has co-editor(s) and authors who are not afraid of pointing fingers. The Board discussed Joe's proposals. Bob Powell noted that it sent a poor message from SSAR if this book series was discontinued. There was discussion of soliciting new ideas for *Herp Conservation* on the new SSAR website, of compiling independent conservation-related manuscripts sent to *JHerp* into a new volume of *Herp. Conservation* (but, would there be interest, would people be willing to pay for this, and how does the impact factor of *Herp. Conservation* compare with that of *JHerp*?), and of publishing SSAR sponsored, conservation-related symposia.

Robert Hansen, Editor of *Herpetological Review*, reported that Volume 44 consisted of 712 pages (a nearly 44% increase since 2009) and Volume 45 is projected to be even larger. Personnel changes include the resignations of Jodi Rowley, Charles Painter, and Beck Werhle. Personnel added, or those shifting to new roles, include Raul Diaz, Jackson Shedd, Jesse Grismer, Ruthe Smith, Drew Davis, Sean Graham, Crystal Kelehear Graham, and Charles Linkem. Bob wished to particularly acknowledge Charles Painter who has been involved with *Herp. Review* since 1995.

Tiffany Doan and Paul Bartelt became Co-Editors of *Journal of Herpetology* at the beginning of 2014. Outgoing co-editors, Erin Muths and Gad Perry, continue to handle papers submitted during 2013 and before, and Erin Muths will remain an associate editor for special invited perspective papers. The editorial office has moved from Texas Tech University to Waldorf College. Former Editor Geoff Smith remains an Associate Editor (AE) for special projects and Paul Andreadis remains the Index Editor.

The AE roster at the end of 2013 contained 24 continuing AEs: Phil Bishop, Xavier Bonnet, Rafe Brown, Tracey Brown, Russ Burke, Steve Corn, Jennifer Gillette, Evan Grant, Brian Greene, James Harris, Tibor Hartel, Toby Hibbitts, Hinrich Kaiser, Nancy Karraker, Edgar Lehr, Marc Mazerolle, Frank Mazzotti, John Rowe, Christopher Salice, Glenn Shea, Stephen Tilley, Tony Tucker, James Watling, and Eric Wild; all four Editors also function as AEs. David Chapple came on as a new AE during 2013. During 2013 and the first half of 2014 the following AEs resigned: Ximena Bernal, Tracey Brown, Tibor Hartel, Toby Hibbitts, Don Miles, Glenn Shea, and Tony Tucker. Two new AEs will be joining *JHerp.* in the second half of 2014: Rocky Parker and Neil Bernstein. Paul Andreadis remains the Index Editor for the Journal. In addition, the Editorial Board has shrunk, to better represent actual involvement; Dirk Bauwens, David Chiszar, Ellen Dawley, James Plaz, Douglas Rossman, Paul Verrell, and Howard Whiteman left the board and David Cundall, David Green, Joe Mendelson, and Gregory Watkins-Colwell joined in 2013, with Brian Crother, William Dunson, Diana Hews, James Petranka, Rick Shine, John Wiens, and Dawn Wilson remaining from the past Board.

The loss of a large number of AEs is a problem that does not have a simple solution. Some of the resignations had to do with expanding duties that did not allow them time to continue "less important" activities such as being an associate editor. Other resignations were due to lack of interest in papers that they were being assigned. Adding new AEs is critical to the functioning of the Journal. The editors are especially interested in expanding representation from Brazil, a country from which they receive many manuscripts each year, and from Asia, which is not represented.

Overall submissions to *JHerp.* declined again in 2013. Submissions for 2014 (108 as of the end of June) are about the same as the number submitted during the same period in 2013. The overall reduction in submissions is a source of concern. Rejection rates have also remained similar to those in recent years (~ 60%). Although the amount of time needed to reach initial decisions increased in 2013, reflecting the ongoing challenge to obtain timely reviews, the editors have been able to reduce the amount of time required to reach a final decision. The wait between acceptance of a paper and publication is down to approximately 9 months. In addition, the establishment of "Online

First" appearance during 2013 means that readers have access to a near-final version almost as soon as a paper as accepted.

During 2013, *JHerp.* received submissions from 33 countries, compared to 37 in 2012, 48 in 2011, 43 in 2010, and 34 in 2009. The leading countries from which manuscripts originate remain the US and Brazil, ranks both countries have held since data became available in 2006. According to the AP "Member Submissions" report, 35% of all submissions in 2013 had one or more authors who are SSAR members, with 65% having none. This remains virtually unchanged since 2010, despite the 2013 decision that members do not need to pay page charges. The editors acknowledge that they may need to better advertise this policy change.

The quality of *JHerp.*, as reflected by the ISI Impact Factor and total citations reported, cannot be measured as the 2013 data were not available as of the writing of the report. As of 2012, *JHerp.* was ranked 87th in the Zoology category, with a 5-year impact factor of 1.2, ahead of *Copeia*, *Amphibia-Reptilia*, and *Herpetological Conservation Biology*, but behind *Herpetological Monographs* and *Herpetologica*.

Over the past few years the editors have implemented a number of new features:

- Optional second-language abstracts Invited long-term perspective
- Inclusion on the back cover of each issue of a world map indicating countries from which published papers are included.
- Full-color, no-cost for graphics
- No page charges for SSAR members
- Online-early appearance of accepted articles
- New Instructions to Authors.
- Associate Editor Lunch

The editors requested input from the Board on the following issues:

• *Publicizing Unique Journal of Herpetology Features.*—Both free color (which is unique among the major U.S.-based herpetological journals) and "Online First" (which is not available from *Copeia*) are two highly desirable features of which many potential authors are not aware. Publicizing these features may lead to more and higher quality submissions to our Journal.

• *Reward for AE service.*—With the loss of five AEs during the first half of 2014, it is apparent that AEs either do not feel that service as AEs is an important usage of their time, or that they do not feel that they are valued by the Society. In addition to the loss of AEs the editors have found widely varying quality among our AEs. The editors would appreciate the Board reconsidering membership or other suitable reward as token recognition to be granted only to those AEs who have served for over a year and completed their reviews in a timely manner.

• *Difficulties in obtaining qualified and timely reviewers.*—This is a huge challenge to the Journal. In addition to finding willing reviewers, the reviewers that do accept almost always take longer than the allotted 30 days.

Standing Committee Chair Reports

The following SSAR members continued their service on the Conservation Committee in 2013–14: Ross Alford, Nicole Angeli, April Barreca, John Jensen, Nancy Karraker, Cecilia Langhorne, Karen Lips, Joe Mendelson, Gad Perry, and Stephen Richter. Susan Walls joined the committee in 2014 and Betsie Rothermel continued to serve as committee chair. In January 2014, the Conservation Committee helped SSAR President Bob Aldridge draft and submit a letter to Texas Parks and Wildlife Department encouraging them to adopt an amendment that would ban the use of noxious and toxic substances to collect nongame wildlife. The proposal would have prohibited the practice of gassing burrows, a frequently used method to collect rattlesnakes. Facing stiff opposition from organizers and supporters of the annual rattlesnake roundup in Sweetwater, the Texas Parks and Wildlife Commission did not take any action following the initial public hearings. The Conservation Committee is exploring ways to use social media to better engage SSAR members to respond to these kinds of issues. Anyone with expertise in this area and an interest in helping with conservation outreach is encouraged to contact a member of the Conservation Committee.

Chair of the Dean Metter Award Committee, Joe Beatty, received seven proposals this year and **Breanna Forester**, a Ph.D. student at Duke University, was selected as the winner. Breanna's proposal was titled "*Evaluating the Implications of Local Adaptation, Habitat Connectivity, and Gene Flow for Terrestrial Salamanders under Global Change.*" Forester will use molecular techniques to detect adaptation, habitat connectivity, and levels of gene flow in natural populations of two species of plethodontid salamanders that inhabit fragmented and warming habitats. One important goal of the study is to determine actions that will be effective in conserving salamander biodiversity under a global climate change regime

The 22nd annual Seibert Awards Competition (Rafe Brown, Chair) was run at the 56th Annual Meeting of SSAR in Albuquerque. There were 55 eligible presentations. The Seibert Award winners for 2013 were: Systematics/Evolution: **Phillip Skipwith** (University of California), coauthors Aaron Bauer, Todd Jackman, "Diversification Rates of New Caledonian Diplodactylid Geckos Inferred From Concatenated and Coalescent Divergence Time Estimates." Ecology: **Julia Riley** (Laurentian University), coauthors Steve Freedberg, Jacqueline Litzgus "Natural Variation in Incubation Temperatures Influence Locomotor Performance of Snapping Turtle (*Chelydra serpentina*) and Painted Turtle (*Chrysemys picta marginata*) Hatchlings." Conservation: **James Baxter-Gilbert** (Laurentian University), coauthors David Lesbarrères, Jacqueline Litzgus, "On The Road Again: The Effectiveness of Mitigation Structures for Reducing Reptile Road Mortality and Maintaining Habitat Continuity." Physiology/Morphology: **Christopher Peterson** (University of Arkansas), coauthors Jason Ortega, Si Hong Park, Irene Hanning, Jacques Hill, Steven Beaupre, "Gastrointestinal Microbes Do Not Influence Digestive Efficiency in African House Snakes (*Boaedon fuliginosus*)." All winners received a check for US $200 and a book from University of California Press. Honorable mentions were: Systematics/Evolution: **Benjamin Lowe** (University of Minnesota), coauthor Kenneth Kozak "Assortative Mating in Hybridizing Southern Appalachian *Plethodon* and Implications for Hybrid Zone Dynamics." Ecology: **James Nifong** (University of Florida), coauthor Brian Silliman, "Impacts of a Large-bodied, Apex Predator (*Alligator mississippiensis* Daudin 1801) on Salt Marsh Food Webs." Conservation: **Rochelle Stiles** (Indiana State University), co-authors Chris La Rue, Michael Hawkins, Michael Lannoo, "Amphibian Response to Restored Prairie Potholes." Physiology/Morphology: **Shelly C. McCain** (Sam Houston State University), coauthors William Lutterschmidt, Clifford Fontenot, Jr., "Behavioral Sensitivity to Salinity and Osmoregulatory Capacity of the Fully Aquatic Salamander, *Amphiuma tridactylum*."

Craig Guyer, newly-appointed Chair of the Herpetology Education Committee, reported that the biggest HEC project

continued to be the Meritorious Teaching Award in Herpetology (MTAH), sponsored by SSAR, HL, and ASIH. Unfortunately, the transition of leadership from last year to this year was slow and suffered from a lack of a document identifying duties and due dates for the HEC chair and HEC members. For that reason, the announcement for MTAH applicants did not appear in the journals and no new applications appeared. However, the applicant pool from the previous year was large and the chair evaluated MTAH candidates remaining in the applicant pool rather than skipping the award for a year.

The HEC approved two applicants for pre-baccalaureate awards: **Alli Metler** from Bartlett, TN (a 5th grader) and **John Matthew Erickson** from Memphis, TN (a 9th grader). The awards provided $390 to cover meeting materials, refreshments, and opening reception tickets for the student and a parent chaperone. President Aldridge requested that the HEC develop guidelines for how these applications will be evaluated, how many awards can reasonably be supported, and whether the awards should include support for the chaperone. The HEC recommends that a maximum of three awards be given, that the awards be restricted to those in 7th through 12th grade, and that it include support for one individual to serve as chaperone. This is contingent upon agreement by the sponsoring societies to support a maximum of ca. $400 per meeting for pre-baccalaureate awardees.

Craig has agreed to chair the committee for a second year to get it back on track. With much help from Cathy Bevier and Greg Watkins-Colwell, a draft document describing the procedures for the chair and committee members has been produced. A mechanism to establish term limits on the committee and to establish an eventual transition of each committee member to the chair position is being created. Cathy Bevier and Greg Watkins-Colwell have earned transition off of the committee and will do so this year. Craig has solicited potential replacements.

The winning paper for the 2013 Kennedy Award (Lynnette Sievert, Committee Chair) is "Joint Space Use in a Parthenogenetic Armenian Rock Lizard (*Darevskia armeniaca*) Suggests Weak Competition among Monoclonal Females" by **Eduard Galoyanin** (*JHerp*. Vol. 47:97–104). Eduard will receive a check for $200 or $400 in SSAR publications.

Kraig Adler, Chair of the Long Range Planning Committee (LRPC), reported that the committee had a rather quiet year during 2012–2013. There was a formal committee meeting, open to the SSAR membership at the JMIH in Albuquerque on July 13th. The major points and decisions were as follows (developments subsequent to the committee meeting are inserted in brackets):

1. SSAR Website.—Joe Mendelson and Raul Diaz reviewed the status of the website and indicated the key point: it must be easily "updatable" so that officers and editors can keep their respective sections current. Various suggestions were made concerning new departments that could be added to our website. We need to avoid redundancy with the ZenScientist site. The SSAR budget and IRS tax forms should be posted in the interests of transparency. It was suggested that some parts of the website should be made available in other languages

2. SSAR Publications Office.—LRPC reviewed the status of our Publications Office in view of the termination of Bibliomania! Breck Bartholomew offered to step down and another book dealer offered to take over, but on careful comparison of all aspects of the two, the committee unanimously recommended to continue its relationship with Breck with thanks for his excellent and loyal service since 2002. Unfortunately, Breck could not attend and thus did not hear all the accolades. Several other factors were discussed: to reduce the size of our stock of publications and to reduce the size of print runs.

3. Mechanisms for Increasing Membership and SSAR's Visibility.—Many ideas were discussed and debated. A major consideration was getting *Herp Review* picked up by *BioOne* or *JSTOR*. [Ann Paterson, Bob Hansen, and Kraig Adler have been dealing with these possibilities since the meeting] It was suggested that we target the large herp expos in Anaheim, Chicago, and Arlington. [Bob Hansen and Kraig have discussed this with Bob Ashley and he agrees to run our full-page, color ad in his program at all meetings at no cost during the 2014–2015 year, by which we could reach more than 10,000 herpers.]

4. Increasing SSAR's Reach Overseas.—Many suggestions were discussed to promote SSAR overseas and to increase our non-USA membership. A special effort should be made to reach students. [Copies of special SSAR membership ads were sent to several overseas meetings.] We could use additional funds to target overseas members. [See "President Aldridge's Referral," below.] Several members now pay the dues for overseas members, usually research colleagues. Ann Paterson is following up on this and hopes to expand this program.

President Aldridge referred the following question to the LRPC in 2013: "I would like the LRPC to consider the merits of setting up a fund in the SSAR budget for subsidizing the dues for (a limited) number of third world members. This fund would be used to subsidize the on-line membership dues. There are a number of options we could use to ensure equal access to potential members from different parts of the world and how to apply for the subsidy. With the on-line option, all the SSAR funds would go back into the budget. This also solves the problem of having different rates for membership based on income. The wording of this benefit is extremely important. Let me know what you think."

This idea arose from the LRPC meeting in Albuquerque. After fleshing out this idea in correspondence between Bob and Kraig, the issue was discussed by the LRPC. To a person, everyone on the LRPC thought the idea of helping overseas herpetologists was a good one. However, a large number of questions arose, among them:

1. *How do we define "Third World"?*
2. *What would the subsidy be?*
3. *First-come, first-served?*
4. *Who makes the decision?*
5. *Would money donated to this fund be diverted from other SSAR causes?*

It soon became clear that such a new program, despite its philosophical merits, created a very large number of issues. The committee was not able to reach a clear position because there were so many divergent views of what we should do. And as one put it, "we are adding a lot of pain for an unspecified but likely small amount of gain." Because our president was reading the commentaries, he could see the dilemma faced by the LRPC.

In mid-November, President Aldridge sent the following message to Kraig Adler: "I think at this point the idea of another category of membership needs to be shelved. The current categories and fees for membership need to be addressed first. So, bottom line, no further action by the LRPC is needed on this issue at this time.

Rafe Brown is Chair of the Local Committee for the 2015 meeting in Lawrence, Kansas (July 30–Aug 2). In his report, he detailed a number of specifics of the upcoming meeting including estimated costs, housing options, and special events (e.g.,

reception for senior herpetologists, plenary lectures, President's Travelogue, symposia, grad student social, picnic, auction, etc.). Some of the old SSAR favorites will be back—live animal displays, field trips, museum tours, herp trivia quizzes. In addition, updated digital versions of "*Herpetologists: Then and Now,"* and "*Amphibians of the Appalachians*," organized by David Dennis, Eric Juterbock, and Kraig Adler will be presented.

The Membership Committee from 2013–2014 included Ann Paterson and Marina Gerson (co-chairs), Jason Brock, Marina Gerson, Tim Halliday, John Herman, Kris Kaiser, Mark Oliva, George Pisani, and Wulf Schleip. Ann Paterson is stepping down as a co-chair after JMIH due to her treasurer responsibilities and Marina Gerson is stepping down as a co-chair at the end of the year due to other obligations. Both are willing to continue to serve on the committee if needed. However, this means that we need to find a new chair or co-chairs for the committee as soon as possible.

During 2013–2014, the Membership Committee continued to stay less active while waiting to see the results of their 2011 proposals. However, the committee did work on the following things: 1) more closely following membership data to examine patterns; 2) developing proposals for possible correspondence with new members and with members who fail to renew; 3) continuing to compile a list of other herpetological societies (both in the U.S. and internationally); and 4) responding to concerns and comments from members and non-members as needed.

Ann and Marina reported that the number of members continues to decrease. Over the next year, it will be important for the membership committee to closely look at patterns in new member subscriptions and in the loss of old members. It may be helpful to track member publications to see the effects of new page charge policies.

Ann and Marina now receive membership data each month, allowing them to monitor changes in membership and to examine whether different activities (such as mailings) affect membership. Even if these activities do not seem to influence membership numbers immediately, they may still increase awareness and have longer-term effects. Marina has analyzed the data in multiple ways, looking at: 1) numbers of individuals in different membership categories; 2) print versus online-only memberships; 3) numbers of members from different countries; 4) length of membership by subscription date (for this category, we do not know the initial date of subscription for members who renew each year but can begin to follow that in future); and 5) date of subscription. From looking at subscription dates, it is clear that most people join or renew between December and March. From looking at subscriptions by country, it appears that there may be opportunities for growth by considering more ways to promote the society internationally, in particular by making international students more aware of grant opportunities and by promoting the manuscript pre-submission service more.

The Mentorship Committee consists of Kris Kaiser (chair), Andrew Durso, Joe Mendelson, and Marion Preest. In its second year, the Mentorship Program aimed to retain a somewhat small size before scaling up in future years. In 2013, they paired eight students from across the societies with mentors. Mentees in the program ranged from pre-baccalaureate to beginning PhD students, and came from all societies. Mentees were all senior graduate students and postdocs. Follow-up surveys showed a general satisfaction with the program, and gave useful feedback for year three of the program. The program this year was advertised on the SSAR website and on the JMIH registration page under "Graduate Student Information," and applications were accepted for both mentors and mentees. For the 2014 meeting, this committee is working to expand the program to a somewhat larger (yet still manageable) size and is working with organizers to include program registration directly into registration for JMIH. They will also work to include all known pre-bacc students who will be attending to pair them with an appropriate mentor.

The Nominations Committee (Robert Espinoza, Chair) compiled a list of nominees for the positions of President-Elect, Treasurer, Secretary, Regular Board Member (two needed), Conservation Board Member (one needed), and At-Large Board Member (one needed). Ann Paterson and Marion Preest were willing to run again for the positions of Treasurer and Secretary, respectively. The nominees:

President-Elect.—Rafael O. de Sa, Richard Shine
Treasurer.—Ann Paterson
Secretary.— Marion Preest
Board Member (Regular).—Robin Andrews, Sara Ruane, Joshua Kapfer, Emily Taylor
Board Member (Conservation).—Kris Kaiser, Kim Lovich
Board Member (At-Large).—Richard Durtsche, Tony Gamble

Rob Denton (Resolutions Chair) presented resolutions at the SSAR Business Meeting in Albuquerque in 2013. These have been published in *Herp. Review*.

Josh Kapfer (Chair, Roger Conant Grants-in-Herpetology Committee) received 81 proposals. Most applications were in the "Laboratory Research" category. In 2013 the Board agreed to double the potential number of winners in each category and to create a new category (Undergraduate Research in Herpetology, five proposals received for 2014 award).

The winners each received $500 and they are:

Conservation.—**Javan Bauder**, University of Massachusetts, "Conservation Genetics of the Federally Threatened Eastern Indigo Snake (*Drymarchon couperi*) in Central Florida." **Bailey Patillo**, University of Memphis, "Salamander Susceptibility and Response to the Amphibian Fungal Pathogen *Batrachochytrium dendrobatidis*."

Education.—**David Steen**, Alabama Natural Heritage Program at Auburn University, "Living Alongside Wildlife: An Online Resource for Amphibian and Reptile Outreach and Conservation."

The Andrew H. Price Field Research Grant-in-Herpetology.—**Brian Folt**, Auburn University, "Does Leaf-drop Phenology Regulate Abundance Cycles of Terrestrial Amphibians and Reptiles in Wet Neotropical Forests?" **Scott Travers**, University of Kansas, "Adaptive Radiation and Community Assembly of Ceratobatrachid Frogs in the Solomon Islands."

Laboratory Research.—**Andrew Frank**, University of Connecticut, "Testing the Parallel Speciation Hypothesis in Western North American Skinks (*Plestiodon*)." **Sofia Prado-Irwin**, San Francisco State University, "Disease Dynamics of the Fungal Pathogen *Batrachochytrium dendrobatidis* in the California Salamander *Ensatina eschscholtzii*."

Travel.—**Christopher Akcali**, University of North Carolina-Chapel Hill, "The Role of Batesian Mimicry in Divergence and Speciation." **Brenna Forester**, Duke University, "Evaluating the Implications of Local Adaptation, Habitat Connectivity, and Gene Flow for Terrestrial Salamanders Under Global Change."

International.—**Nina Seren,** CIBIO Institute (Portugal), "Genetic Response to Heavy Metal Exposure in Amphibian Larvae Under Laboratory Experimental Conditions." **Marta**

Vidal-Garcia, The Australian National University, "Unraveling Body Shape Evolution in Australo-Papuan Myobatrachid Frogs."

Undergraduate Research.—**Renae Reed**, Peninsula College, "Quantifying an Active Population of Central America's Rarest Turtle, *K. angustipons*."

Since Spring 2013, the Website Subcommittee has been comprised of Carol Spencer, Raul Diaz, Vincent Farallo, Michelle Koo, Joe Mendelson, and Todd Pierson. This committee has accomplished an ambitious agenda with the ultimate goal of a new website and content management system that will benefit both visitors to the site as well as the future committee members who will need to maintain and update the site.

The Committee solicited bids from three experienced website designers. In August, 2013, Trish Roque (University of California Museum of Paleontology employee and independent website designer, who develops in WordPress) was selected. The committee felt Trish provided the most comprehensive and organized estimate and timeline for completion of the website. She designs eye-catching dynamic websites and has experience with academic users who need to keep detailed content current without depending on a coder for all updates. Once her website architecture and design is in place, Philip Kahn, web programmer, was selected to help with website maintenance/programming and to build any database or other programming needs in the future.

The committee has met more than five times in conference calls in 2014, with additional meetings with Michelle and Trish in person. The design and implementation is moving forward; the new website is based on the latest version of WordPress and has many customizations of specialized WordPress plugins to meet our desired features list. Although not designed specifically for mobile devices, the new website will be more compatible and flexible on different devices and platforms (e.g., OS).

As of 8 July 2014, all committee members have contributed to editing content and information for pages and currently Michelle, Raul, and Joe are putting this content into place on the website. Michelle created WordPress accounts for all website committee members and will proceed to create accounts for associated directors and SSAR personnel. These accounts have varying privileges, as some folks are allowed full editing and page changing rights whereas others can only edit and add text to pages. We are still editing the website and plan to make it public on 26 July 2014, four days before the next JMIH meeting and SSAR board meeting on 30 July 2014. The website will be live and replace the old site at http://ssarherps.org. The committee welcomes constructive comments from the public and members of the executive committee, directors, and editors.

Brian Crother, Chair, Standard English and Scientific Names Committee, reported that with the delay in posting the 7th Edition published for the 2012 World Congress, the SESNC developed a 7.1 edition specifically for online access. By the time of the 2014 JMIH, the new edition should be live online and dynamically updateable. Each new update to the online version will be recognized by changing the edition number, e.g., 7.1, 7.2…7.35, etc., until another hard copy version is published. Brian thanks Raul Diaz and his committee for their hard work in making the list a living document. Steven Tilley has been the chair of the Salamander Subcommittee and David Wake has been a member of that committee. They are stepping down after the new e-version is completed. Brian wants to thank them and recognize their excellent work on the Names Committee.

The third annual SSAR Student Poster Awards (Tiffany Doan, Chair) were presented at the Annual Meeting of the SSAR in Albuquerque. There were 40 eligible posters. In recognition of outstanding student poster presentations at the annual meeting, the following awards (a check for US $100 and a book from University of California Press) were made: Evolution, Genetics, & Systematics: **Shuangying Yu**, Texas Tech University, "Endosulfan and alpha-cypermethrin inhibit repair of DNA photo adducts and decrease transcription of nucleotide excision repair genes in *Xenopus laevis* embryos." Conservation & Management: **Katherine O'Donnell**, (University of Missouri), "Initial terrestrial salamander responses to prescribed fire and timber harvest in southeast Missouri." Ecology, Natural History, Distribution, & Behavior: **Kristin Winchell**, University of Massachusetts, Boston, "Phenotypic shifts in urban populations of the tropical lizard, *Anolis cristatellus*."

In 2013, Mike Jorgensen and Vincent Farallo (Co-Chairs, Student Travel Awards Committee) received 14 applications for the travel award, substantially lower than the numbers in previous years. The main role of the Student Travel Awards Committee is to accept applications for the award and coordinate with the awardees to supervise the silent auction table at the annual meeting; however, both Mike Jorgenson and Vincent Farallo were unable to attend the meeting to direct awardees and oversee the silent auction table. Two colleagues, Matthew Lattanzio and Christopher Howey, were kind enough to help take over this duty for the meeting in Albuquerque. Students receiving awards helped supervise the silent auction table as has been done in previous years. The Silent Auction raised $869.

Coordinators' Reports

Election Officer, Dan Noble, reported that no election was held in 2013.

In 2013, the SSAR/HL Live Auction returned to the "normal" operation of generating funds to be split between SSAR and HL. SSAR funds are used to support student travel awards. The Live Auction was organized by Greg Watkins-Colwell, Kirsten Nicholson, and Meredith Mahoney. This year we saw the return of Samantha Kahl, who had served as a student volunteer many times in the past, and returned this year to help organize. Efforts were made to include as many different auctioneers (with different auctioning styles) as possible and to rely upon the help of students who had not helped with the auction in the past. The live auction made $5,758. After all costs, the remainder was split 50-50 with HL, leaving $2,023.07 to help fund student travel awards.

Greg, Meredith, and Kirsten have been in discussion regarding the future of this committee. Greg will step down as the Chair of the Auction Committee following the Live Auction at the 2015 SSAR meeting in Lawrence, Kansas and Kirsten will step down after the 2014 meeting.

Representative to AIBS and BioOne, Al Savitzky, reported that BioOne, a nonprofit electronic publishing consortium, continues to provide online publishing services for the society and to return both royalties and profit-sharing proceeds to its member publishers. After several years, Al has resumed attendance at the P&P meetings as he was elected to the Board of Directors of BioOne. The P&P meetings provide an opportunity for the BioOne staff to report on the status of the organization, describe the financial return to member publishers, and provide background on issues relevant to online publishing and scholarly societies. Details regarding BioOne, including the presentations given from past P&P Meetings, can be found at http://

www.bioone.org/. This year BioOne reported that in 2013, its twelfth year online, the collection exceeded one million pages of content and over 13 million site hits. Net sales increased by 4.7% over 2012. Presentations at the meeting included those on MOOC's, the challenges of marketing scholarly journals in India, *Elementa: Science of the Anthropocene*, a new open-access, online-only journal launched in December 2013 by BioOne, and an algorithm that has been developed to assist society publishers in determining the costs and benefits of open-access publishing, as increasingly mandated by federal funding agencies. The algorithm considers such factors as embargo length and the proportion of content that is federally funded (and thus subject to OA mandate). The algorithm will be made freely available to BioOne member publishers.

The American Institute of Biological Sciences (AIBS) is an umbrella organization that serves about 160 member societies and organizations (MSOs), most of them in the broad areas of organismal biology and ecology. AIBS has been building upon several surveys it has conducted on the interests and activities of both individual researchers and biological societies. The 2013 annual meeting of the AIBS Council involved a discussion of trends, opportunities, and challenges facing the biological sciences and scholarly societies focused on biology. In addition to providing advice to its MSOs through its surveys and explorations of leadership issues in biology, AIBS continues to be active in a number of areas of immediate interest to our society's members. These include activities related to undergraduate and graduate education, natural history collections, and representing the interests of organismal biologists and ecologists to Congress. Society members are encouraged to register with the AIBS Legislative Action Center (LAC; http://policy.aibs.org/), which provides immediate alerts regarding relevant legislation and simplifies contacting individual legislators to express an opinion on those issues, many of which are related to conservation or the federal funding of science. Al's presentation lead into a long discussion of membership issues facing all or most scientific societies, how to reduce competition between societies, how to retain individual identities if societies merge, and what is the future of societies in general.

This year two symposium proposals were submitted to Symposium Coordinator Dick Durtsche for SSAR sponsorship at the 2015 SSAR meetings at the University of Kansas, with only one requesting funding.

The first proposal entitled "*Research Frontiers in Integrative Organismal Biology: Herpetological Horizons*" was submitted by Rafe Brown and Richard Glor. This symposium will bring together an array of mostly early-career faculty who use reptiles and amphibians in integrative studies of evolutionary biology. The organizers seek sponsorship of $1500 for travel and symposium dinner expenses. The symposium proposal was sent out for external review, and reviewer comments and the proposal were submitted to the SSAR Board for consideration of sponsorship.
The second proposal (confidential until the appearance of an announcement in an upcoming issue of *Herp. Review*) was submitted by David Cannatella, Anna Maglia, and David Blackburn as co-organizers. The symposium proposal does not request any funding, only SSAR sponsorship and it was sent to the SSAR Board for consideration.

New Business

Vinny Farallo and Todd Pierson (Wesite Subcommittee) showed the Board the new SSAR website and noted that it will be easy to update. A guideline for editing will be provided. The Board made a few suggestions about layout.

Greg Watkins-Colwell raised the issue of sponsoring pre-baccalaureate students (and their chaperones). Greg will ask the HEC to come up with criteria to determine how to choose which students to sponsor.

There was some discussion of whether SSAR wanted to make available to members an SSAR credit card. SSAR would receive a fixed amount the first time each card is used and then a much smaller amount with subsequent uses. The Board seemed interested in this idea and asked Treasurer Paterson to look into the details of this and come back to the Board with additional information.

President-Elect Bauer presented a request from Kraig Adler to use up to $15,000 from his Publication Reserve to support the attendance of senior herpetologists at the SSAR meeting in Lawrence in 2015. The Board voted unanimously to support this request. In later discussions it was decided to use money from the *Contributions to Herpetology* budget, and then transfer funds from the Reserve budget to the *Contributions* budget.

The Board then turned to brief consideration of ways in which SSAR and Center for North American Herpetology (CNAH) might work together. Although members of the Board seemed in favor of this idea, no specific recommendations were made. Earlier, Peter Uetz had initiated an e-mail discussion of the relationship between SSAR and the Reptile Database. It was agreed that this is a matter for the LRPC to discuss.

Provision of childcare at the annual meeting was then discussed briefly. There was general support from the Board, however the matter of liability was raised. It was recognized that there were questions that needed answering before SSAR could move on this. Erin Muths suggested that a committee be formed to investigate these issues.

The Board then turned to the 2015 budget. A balanced budget of $304,440 for 2015 was approved by the Board.
The meeting was adjourned at 1346 h.

SSAR Business Meeting

The Annual SSAR Business Meeting was called to order by President Aldridge (1800 h, Aug 2nd). Ninety-two members of SSAR were present (Fig. 8). Officers, Editors, and Committee Chairs who were at the Business Meeting introduced themselves

to the other attendees and gave brief summaries of their Annual Reports and relevant information from the Board Meeting. There was applause given to acknowledge Erin Muths and Gad Perry who are stepping down as co-editors of *JHerp* and Tiffany Doan and Paul Bartelt who are replacing them. The outgoing and incoming editors mentioned some of the substantial perks of publishing in *JHerp*—free color, no page charges for members, online access immediately available after acceptance of most manuscripts, etc. Rafe Brown and Rich Glor did a great job hyping the 2015 meeting in Kansas. They specifically mentioned the events recognizing senior herpetologists, the live animal displays, the auctions, field trips, and the low cost of accommodation.

Rob Denton then read the following resolutions: "SSAR wishes to thank a large number of individuals for service to the Society. Even though outgoing co-editors of *Journal of Herpetology*, Erin Muths and Gad Perry, remain highly active with the journal, we wish to thank them at this stage for their several years of service to the Society in this capacity. Erin and Gad took over as editors with fairly short notice in 2010, and during their tenure they ushered in some important and very welcome changes to the journal. We would also like to acknowledge incoming co-editors Tiffany Doan and Paul Bartelt and thank them both for stepping unto this role. The following Associate Editors of *JHerp*.— Ximena Bernal, Tracey Brown, Tibor Hartel, Toby Hibbitts, Don Miles, Glenn Shea, and Tony Tucker—stepped down and we thank them for their work. In addition, we are grateful to the following members of the Editorial Board of *JHerp*. who have resigned recently: Dirk Bauwens, David Chiszar, Ellen Dawley, James Plaz, Douglas Rossman, Paul Verrell, and Howard Whiteman. At *Herpetological Review*, Jodi Rowley, Charles Painter, Jackson Shedd, Raul Diaz, and Beck Werhle concluded excellent runs of service. Bob Hansen wishes to particularly acknowledge Charles Painter, outgoing Section Editor for Natural History Notes. The Society joins Editors of *Catalogue of American Amphibians and Reptiles*, Travis LaDuc and Chris Bell, in thanking Bob Powell, Breck Bartholomew, and Ruthe Smith for their help in navigating through the logistics of editing this series. We thank Greg Watkins-Colwell, who was a member of the Herpetology Education Committee for several years, and Cathy Bevier, who was chair of the same committee for many years and then continued as a member. Both are stepping down. We particularly wish to thank the many hard-working members of the Website Committee: Carol Spencer (chair), Joe Mendelson, Raul Diaz, Vincent Farallo, Michelle Koo, and Todd Pierson. The new and extensively redesigned SSAR website is due to go live within a few days or weeks and we look forward to feedback from society members. We thank this year's SSAR President's Travelogue speaker, David Blackburn, for his excellent presentation "Adventures with African Amphibians." Thanks to John Sulzycki at CRC Press for his continued support of Seibert Award and Student Poster competitions. Thanks to both Ann Paterson and Marina Gerson for co-chairing the Membership Committee for the past several years. Thanks to Bobby Espinoza, chair of the Nominations Committee, for generating a strong slate of nominees for the upcoming 2014 election. Congratulations to the fifth winner of the SSAR/HL/ASIH Meritorious Teaching Award in Herpetology, Dr. Alan Richmond. Thanks again to those who served as mentors for students attending JMIH in our new and successful Mentorship Program led by Kris Kaiser and Andrew Durso. SSAR and Standard English and Scientific Names Committee Chair, Brian Crother, wish to acknowledge the long-standing contributions of Steven Tilley and David Wake to that committee. We thank Matthew Lattanzio and

Christopher Howe, who temporarily stepped in to take over Student Travel Awards Committee duties during the 2013 Albuquerque meeting. After tomorrow night's auction, Kirsten Nicholson is stepping down as a member of the Live Auction Committee, a position for which she has served ably and with enthusiasm for many years. We thank her. Finally, we are excited about our 2015 Annual Meeting with PARC, Kansas Herpetological Society, Missouri Herpetological Society, Arkansas Herpetological Society, and CNAH, to be held on the campus of the University of Kansas. We repeat our thanks from last year to the members of the Local Committee —Rafe Brown (Chair), Bill Duellman, Rich Glor, Linda Trueb, and George Pisani—for the extensive work they have put into the planning for this much-anticipated meeting."

Henri Seibert, Student Poster, and Travel Awards were presented by Rafe Brown, Tiffany Doan, and Vinny Farallo, respectively (Figs. 9, 10). There was then a very speedy handing over of the gavel from President-Aldridge to President-Elect Bauer (Fig. 11) and the meeting was adjourned.

List of Abbreviations Used

AES - American Elasmobranch Society
AIBS - American Institute of Biological Sciences
AP - Allen Press
ASIH - American Society for Ichthyology and Herpetology
CNAH - Center for North American Herpetology
HL - The Herpetologists' League
IRS - Internal Revenue Service
JMIH - Joint Meeting of Ichthyologists and Herpetologists
LRPC - Long Range Planning Committee
MOOC - Massive Open Online Course
MSO - Member Societies and Organizations
MTAH - meritorious Teaching Award in Herpetology
OA - Open Access
PARC - Partners in Amphibian and Reptile Conservation

—Respectfully submitted by **MARION PREEST**, *SSAR Secretary*

SSAR Election Results

Results of the 2014 SSAR election are as follows:

President-Elect: **Rick Shine**
Treasurer: **Ann Paterson**
Secretary: **Marion Preest**
Board Members (Regular): **Robin Andrews, Emily Taylor**
Board Member (Conservation): **Kim Lovich**
Board Member (At-Large): **Tony Gamble**

Thank you to all of the nominees who agreed to stand for positions, Robert Espinoza (Chair) and other members of the Nominations Committee, and Dan Noble (Election Officer).

2014 Seibert Awards Announced

The 23rd annual SSAR Seibert Awards were presented at the 57th Annual Meeting of the SSAR with the Joint Meeting of Ichthyologists and Herpetologists, hosted by the University of Tennessee, Chattanooga, 30 July–3 August 2014. These awards are named in honor of Henri C. Seibert, an avid supporter of SSAR who served as an officer for over 20 years. In recognition of outstanding student presentations at the annual meeting, an award was given in each of the following categories: Evolution/Systematics (5 presentations), Ecology (14 presentations), Physiology/Morphology (4 presentations) and Conservation (6 presentations). All awardees received a check for U.S. $200 and a book from CRC Press.

The Winners:

Systematics/Evolution.—**Elyse Freitas** et al. (Villanova University), "Molecular Phylogenetics and Patterns of Limb Loss in the Genus *Scelotes*."

Ecology.—**Chris Thawley** et al. (Penn State University), "The cost and benefits of adaptation: a case study using native fence lizards and invasive fire ants."

Conservation.—**Drew Davis** et al. (University of South Dakota), "Effects of Agricultural Tile Drainage on Amphibians in Eastern South Dakota."

Physiology/Morphology.—**Patrick Moldowan** et al. (Laurentian University), "Turtles with teeth: tomiodont morphology and functional significance in the Painted Turtle (*Chrysemys picta*)."

Honorable Mentions:

Systematics/Evolution.—**Rachel Skinner** et al. (Villanova University), "Phylogenetic Relationships of South African Geckos in *Pachydactylus geitje* Species Complex (Squamata: Gekkonidae)."

Ecology.— **(A) Meagan Thomas** and Steve Mullin (Eastern Illinois University), "Quantifying dietary overlap in a community of invertebrate feeding snakes." *Special undergraduate honorable mention!* **(B) Mark Herr** et al. (James Cook University), "Stressed snakes strike first: hormone levels and defensive behavior in free-ranging cottonmouths."

Conservation.—**Brian Crawford** et al. (University of Georgia), "Does pride work? Evaluating an NGO's integrative model for promoting community conservation behavior."

Physiology/Morphology.—**Matthew Dickson** et al. (California State - Northridge), "Rapidly adapting to the neighborhood: physiological responses of Mediterranean House Geckos to their introduced climates."

SSAR would like to thank this year's Seibert Judges Committee for their service: Jacqueline Litzgus, Laine Giovanetto, Richard Durtsche, Eric Juterbock, Phillip Bishop; William Peterman, David Blackburn, Matthew Klukowski, Richard Glor, Charles Linkem, and Rafe Brown (Chair).

SSAR Student Poster Award Winners for 2014 Announced

The fourth annual SSAR Student Poster Awards were presented at the 57th Annual Meeting of the SSAR and the Joint Meeting of Ichthyology and Herpetology in Chattanooga, Tennessee, 30 July–3 August 2014. This year there were 40 eligible posters. In recognition of outstanding student poster presentations at the annual meeting, a single award was given in each of the following categories: Physiology & Morphology (8 presentations), Ecology, Natural History, Distribution, & Behavior (22 presentations),

and Conservation & Management (10 presentations). Because few students entered the Evolution, Genetics, & Systematics category, those students were placed in other categories and no award was given in that category. All awardees received a check for US $200 and a book from CRC Press.

The Winners:

Physiology & Morphology.—**Krista Mougey**, Texas Tech University, "Thermal ecology and locomotor performance of the critically endangered Stout Iguana *Cyclura pinguis*."

Conservation & Management.—**Grant Connette**, University of Missouri, "Historic timber harvest predicts abundance but not genetic diversity of a terrestrial salamander, *Plethodon shermani*."

Ecology, Natural History, Distribution, & Behavior.—**E. Alexander Rohtla**, Villanova University, "Advertisement calls of the thick-toed geckos (Reptilia: Gekkonidae: *Pachydactylus*)."

SSAR thanks this year's judges: Tiffany Doan (Chair, State College of Florida, Manatee-Sarasota), Marina Gerson (California State University, Stanislaus), Jon Davenport (University of Montana), Bruce Kingsbury (Indiana-Purdue University Fort Wayne), Kristen Cecala (Sewanee-University of the South), Thomas Lozito (University of Pittsburgh), and Frances Irish (Moravian College).

NEWSNOTES

Global Ranavirus Consortium

The scientific community is increasingly aware that emerging infectious diseases pose a significant threat to global biodiversity. A group of viruses in the genus *Ranavirus* (Family Iridoviridae) cause disease in amphibians, reptiles and fish, and appear to be emerging in some populations. *Ranavirus*-associated die-offs in larval and adult amphibians have been documented in the Americas, Europe, and Asia, with death rates often exceeding 90% during an outbreak. *Ranavirus* infections also have been reported in wild and cultured fish populations worldwide. While research on reptiles has been slower to accumulate, recent evidence suggests that ranaviruses are capable of causing morbidity and mortality in free-ranging populations. The capability of ranaviruses causing disease in poikilothermic animals belonging to three vertebrate classes emphasizes the potential risk of these pathogens to global biodiversity.

The Global Ranavirus Consortium (GRC) was formed following the First International Symposium on Ranaviruses. The goal of the GRC is to facilitate communication and collaboration among scientists and veterinarians conducting research on ranaviruses and diagnosing cases of ranaviral disease. Since formation, the GRC has published 3 popular articles on the 2011 Symposium and organized the Second International Symposium on Ranaviruses, which was held 27–29 July 2013 concurrently with the International Conference of the Wildlife Disease Association in Knoxville, Tennessee, USA. The Third International Symposium on Ranaviruses will be held 30 May–1 June 2015 at the University of Florida in Gainesville, Florida, USA. The GRC recently hosted a workshop on ranaviruses in Harbin, China.

The GRC was recently approved to write the first book on ranaviruses, which will be published as an eBook (i.e., chapters can be purchased independently) by Springer. Target publication date is November 2014. The GRC formed global regional discussion groups (see regional contact below) to help facilitate the transfer of information among scientists, and created a website with recent publications. To improve understanding of the global distribution of ranaviruses, the GRC is working to secure funds to create a Global Ranavirus Reporting System. The Executive Board has finalized bylaws for the GRC, and will be offering membership options in 2014.

If you would like to be listed as a GRC scientist or contribute to activities, please contact Dr. Matthew Gray or your regional representative on the Executive Board (see below). We also encourage interested students and scientists to join the GRC LISTSERV.

To post to the GRC listserv, send an e-mail message to GRC@LISTSERV.UTK.EDU. Appropriate content for posting includes (but is not limited to) sharing information on recent ranavirus die-offs, research findings, or publications; asking questions or discussing topics related to ranaviruses or ranaviral disease; and providing information about GRC activities. Anyone can post to the listserv (including non-members) and all postings are archived and can be viewed by the public. If you would like to become a member of the GRC listserv, you can join at this website: http://listserv.utk.edu/cgi-bin/wa?A0=GRC.

GRC Executive Board.—Matthew Gray, Ph.D., Director, University of Tennessee; Jesse Brunner, Ph.D., Associate Director, Washington State University; Amanda Duffus, Ph.D., Secretary/Treasurer, Gordon College; Yumi Une, D.V.M., Ph.D., Asia Representative, Azabu University; Ellen Ariel, Ph.D., Australia Representative, James Cook University; Rachel Marschang, D.V.M., Ph.D., Europe Representative, Universität Hohenheim; Thomas Waltzek, D.V.M., Ph.D., North America Representative, University of Florida; Rolando Mazzoni, D.V.M., Ph.D., South America Representative, Universidade Federal de Goiás; Greg Chinchar, Ph.D., Honorary Advisor, University of Mississippi Medical Center.

Updated Standard Symbolic Codes for Institutional Resource Collections in Herpetology & Ichthyology

A new up-to-date version (v.5) of the *Standard Symbolic Codes for Institutional Resource Collections in Herpetology & Ichthyology* is now available via the ASIH website: http://asih.org (under Resources tab).

The new list contains 1633 abbreviation records including 125 newly added, as well as important corrections to previously listed abbreviations. Authors are encouraged to use/cite the new list. Older versions of the list should be deleted. Citations of <http://www.asih.org/node/204> should be avoided, as that URL no longer links to a list of collection codes.

Please send additions, corrections, and updates, however minor, to Mark Sabaj Pérez at sabaj@ansp.org.

ARMI Receives Special Recognition

The Wildlife Society's Biometrics Working Group provides for a Special Recognition Award meant to highlight a group or individual that has made an outstanding contribution to the development and application of quantitative methods to the fields of wildlife science and management. This year the award is presented to the Amphibian Research and Monitoring Initiative (ARMI), implemented by the U.S. Geological Survey and the U.S. Fish and Wildlife Service. ARMI has shown a deep appreciation for biometrical methods and their importance for drawing inferences about biological populations and communities. Most significantly ARMI propelled forward the development of a class of models (occupancy) that is now used worldwide by ecologists and conservation biologists. This funding support was largely responsible for dozens of papers on the development of occupancy modeling and for the 2006 book (MacKenzie et al. 2006. *Occupancy Estimation and Modeling: Inferring Patterns and Dynamics of Species Occurrence*. Elsevier, San Diego, California; see Acknowledgments in this book) summarizing developments to that time. This development has not only been useful to ARMI projects, but has also benefited the worldwide community of animal ecologists, wildlife managers, and the field of biometrics.

The Wildlife Society Recognizes Ken Dodd

Each year The Wildlife Society, which boasts 10,000 members, selects one authored book to receive its "Outstanding Book Award." This year they honored an anuran title, Ken Dodd's *Frogs of the United States and Canada*. Ken's two-volume work is certainly the most thorough reference available on frogs of the region. Previous winners of this award include Carl Ernst and Jeff Lovich for *Turtles of the United States and Canada (2011)*, James E. Petranka for *Salamanders of the United States and Canada* (1998), E. O. Wilson for *Diversity of Life* (1992), and Walter Auffenberg for *The Behavioral Ecology of the Komodo Monitor* (1983). SSAR congratulates Ken Dodd for this honor.

Vogt Receives 9th Annual Behler Conservation Award

The Behler Turtle Conservation Award is a major annual international award honoring excellence in the field of tortoise and freshwater turtle conservation and biology, and leadership in the chelonian conservation and biology community. The award is co-presented by the Turtle Survival Alliance (TSA), the IUCN/SSC Tortoise and Freshwater Turtle Specialist Group (TFTSG), the Turtle Conservancy (TC), and the Turtle Conservation Fund (TCF, the four organizations most closely tied to the turtle conservation legacy of John Behler. The award honors and commemorates the memory and legacy of John L. Behler (1943–2006), late Curator of Herpetology at the Bronx Zoo, Wildlife Conservation Society, New York. John was also Chair and Co-Chair of the IUCN/SSC Tortoise and Freshwater Turtle Specialist Group and a founding board member of both the TSA and TCF, as well as a founding board member of the Chelonian Conservation Center, later renamed the Behler Conservation Center in his honor by the recently created umbrella organization, Turtle Conservancy.

Not many scientists can say that they have altered the course of an entire field of study; Richard C. (Dick) Vogt can, not once, but now twice! His pioneering work with Jim Bull in the late 1970s on temperature-dependent sex determination (published in the journal *Science*) forever changed how we view the evolution and conservation of chelonians. Astoundingly, he has followed up this incredible career-defining achievement with yet another—his most recent work on chelonian vocalization has again turned the turtle world upside down and is setting a new path for how we practice turtle conservation.

Dick and his students have not only shown that a number of turtle species are "talking", but that there is communication between adult females and hatchlings in the Giant Amazonian River Turtle (*Podocnemis expansa*). This is the first documented evidence of post-hatching parental care in chelonians. Our conservation community must now consider how these findings might affect how we headstart this and other species. We must ask ourselves if we are disrupting important transference of learned behaviors from mother to offspring by keeping hatchlings in captivity for weeks to years before their release. We may unwittingly be doing more harm than good, much like how many early turtle conservationists incubated turtle eggs at cool temperatures, thereby producing only males, before Dick's seminal work demonstrated the error of their ways.

After nearly twenty years of living in Mexico—which culminated in his most recent book *Turtles of Mexico: Land and Freshwater Forms*, co-authored with the late John Legler, Dick yet again decided to challenge himself and begin anew. Dick's next project is to finish John Legler's long-awaited book, *Turtles of Australia*. SSAR congratulates Dick on this worthy honor.

—Excerpted and edited from *Turtle Survival Magazine* (2014:72–73, Brian D. Horne and Andrew Walde).

Reptile Database Update

The latest version of the Reptile Database (released 1 Dec 2014) features 10,119 species (including 139 described this year) and 35,615 references (including 1,203 published this year). The Reptile Database has also established a Scientific Advisory Board (SAB) that will help to make strategic decisions but will also advise with controversial taxonomic issues. For instance, the SAB recommended not to break up the boas into multiple smaller families as recently proposed by Pyron et al. (2014. Zootaxa 3846[2]:249–260). The database now also offers materials for herpetology classes with assignments for students to read and

curate herp papers. This should help students to hone their skills in reading and analyzing the primary literature but also supply the database with new information. For more details see http://www.reptile-database.org.

MEETINGS

Meeting announcement information should be sent directly to the Editor (herpreview@gmail.com) well in advance of the event. We also welcome brief reports of meetings; please consult the Editor for details.

Martin John Fouquette, Jr., 1930–2014

BRIAN K. SULLIVAN*
JAMES E. PLATZ
Arizona State University, PO Box 37100, Phoenix, Arizona 85022, USA

**e-mail: bsullivan@asu.edu*

Our major professor, Martin John Fouquette, Jr., or "Jack" as he was known to one and all, provided over 46 years of service to students of three different academic institutions (University of Florida, 1959–1961; University of Southwestern Louisiana, 1961–1965; Arizona State University, 1965–2005, plus 2005–2014 as an emeritus faculty member). As former students, we pay tribute to Jack herein by reviewing his distinctive qualities as a person and a scientist. We draw special attention to his unique approach to mentoring that we shared with all his graduate students from the early 1960s through to the beginning of the 21st Century. From 1960 through 2002, Jack advised 9 PhD and 15 MA students, many of whom went on to successful careers in herpetology. Jack was a life member of all three North America-based herpetological societies (ASIH, HL, SSAR), and he loved going to meetings (Fig. 1), in part because of his affection for his students and his desire to see them do well.

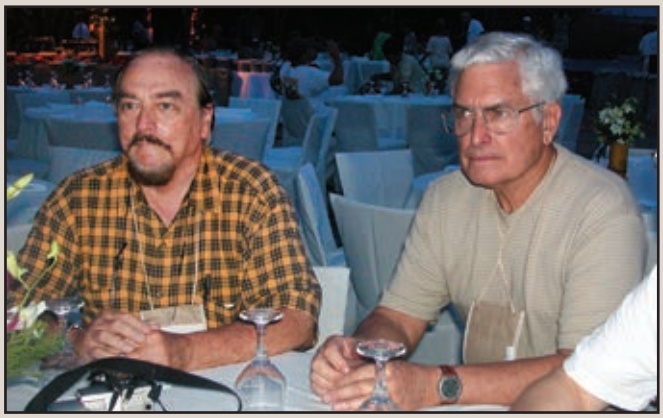

PHOTO COURTESY OF DAVE HARDY

FIG. 1. Jack loved attending meetings; here is Jack, next to Dave Hardy, in Manaus, Brazil, 2003, at the World Congress of Herpetology.

Martin J. Fouquette was born in Philadelphia, Pennsylvania, 14 June 1930, but moved to Huntington, a small town in West Virginia, within two years, before settling in Kerrville, Texas, just five years later. He had no memories of Philadelphia, but did recall a dramatic roof-top rescue by motor boat following the 1936 flooding of the Ohio River in West Virginia when water reached the second story of their house. Perhaps that experience was strongly imprinted—he told us often about how a flood event could be extremely useful for "herping," such as the rare flooding of the Painted Rock Reservoir on the Gila River in the 1970s, which led to the opportunity for his graduate students to collect hundreds of snakes isolated on ever-shrinking islands. Students that knew of Jack's love of early westerns on TV ("Have Gun, Will Travel" was a favorite) always assumed that any appearances to the contrary, Jack was taken with rural Texas where he spent his formative years.

FIG. 2. Jim Delahoussaye and Jack Fouquette (left), in the field recording chorus frogs somewhere in the southeastern US, 1964. Proofs from a school newspaper article, University of Southwestern Louisiana, 1964.

His early days in Texas led to his matriculation at the University of Texas, Austin, a result of simple geographic proximity. By the finish of high school he loved snakes, but his parents—like those of so many budding herpetologists!—had convinced him there were "no jobs" in herpetology, so he initially majored in chemistry. Shortly after arriving at UT, however, exposure to the lab group under Frank Blair influenced him to change his major to zoology. He finished his BA, and pursued a Masters under Blair, focusing on gartersnakes, his first love (Fouquette 1954). Afterwards, he joined the USAAF to avoid serving in the infantry even though it entailed four years of service instead of two. He requested that he be assigned to Panama, where he served as a navigator on a seaplane, a Grumman S-16, in the air rescue branch of the Air Force, because he imagined it would afford more research opportunities. He discussed matters with Blair. At a time when (apparently) major professors like Frank Blair could provide adequate direction in a few short sentences, Jack was advised to simply purchase the requisite (and newly developed at the time) recording equipment so he could gather data on calling in various hylid frogs in Central America. Blair advised that by purchasing a recorder, he could spend time off in the Canal Zone recording frogs, which he did (e.g., Fouquette 1960a, b, c; Littlejohn and Fouquette 1960); subsequently he used those data to finish his PhD at UT Austin (1959), just two years after his release from the Air Force in 1957.

Living in Austin during the 1950s, Jack roomed with Ralph Axtell; he told Ralph the story of an amazing night-driving experience one stormy evening in Panama: "I found a big snake crossing the road late at night as I returned home; it was dark and I was in a hurry, so I just threw it in the trunk…when I opened it in the morning, there was a huge bushmaster there!" Consistent with his typically understated delivery, Jack never offered any additional details as to the method of capture or subsequent processing of the specimen. After working with tropical hylids (Fouquette 1958, 1961a, b, 1968a,c; Duellman and Fouquette 1968), his subsequent time in the southeastern USA consolidated his interest in the chorus frogs and other hylids of the Gulf Coast states, leading to some of his most important contributions (e.g., Littlejohn et al. 1960), a lifelong interest in the anurans of that region (Fig. 2), and the honor of having a recently described taxon named for him (Lemmon et al. 2008).

Jack had been quite happy in his first two academic positions, the first at the University of Florida and the second at the University of Southwestern Louisiana. Still, he was excited about the prospects of establishing a bioacoustics research program in the arid Southwest, in part because he was already aware of the opportunities the deserts provided given prior pioneering work by both Frank Blair and his brother, A. Pat Blair. His intimate knowledge of what the Blair brothers had accomplished in southwestern Utah paid dividends decades later when he provided one of us (BKS) with detailed information on the mating behavior of Arizona Toads, derived from work by both Frank and Pat, and Jack's firsthand experience with bufonids in the 1960s and 1970s (e.g., Fouquette 1968b, 1970, 1980).

The 1970s were productive for Jack in part because he coauthored a number of papers with students (e.g., Fouquette and Pyburn 1972; Pyburn and Fouquette 1971; Fouquette and Delahoussaye 1977; Mitchell and Fouquette 1978). In 1975 he published one of the few definitive empirical studies of reproductive character displacement, reporting on this rarely documented but widely discussed phenomenon in chorus frogs of the southeastern USA (Fouquette 1975). On either side of that date, as major professor or committee member, he signed off on the dissertations and theses of students that went on to have profound impacts on the herpetology of the Southwest (e.g., Platz and Platz 1973; Congdon et al. 1974). Laurie Vitt, a widely renowned herpetologist with hundreds of publications and thousands of citations to those contributions to his credit, represents one of Jack's most productive students during the decade of the 70s.

"*…Jack was simply one of the nicest people I ever encountered—he wasn't pushy, he wasn't arrogant, and he seemed to have a level of integrity that I now know is much rarer in academia than we would like to think…when I arrived at ASU, Jack's students thought the world of him, which of course was a good sign.*"

—Laurie Vitt

It was also during the 1970s, when interest in sexual selection and speciation was peaking, that Jack's empirical contribution on character displacement in chorus frogs appeared—highly regarded as one of the only examples accepted by one and all within this contentious field. Jack's meticulous and careful approach to data collection was truly tested when during the final stages of his last NSF grant his PhD student was killed in a car crash while returning to Arizona, with the loss of a considerable amount of the data they had collected. We have often wondered if that tragic accident was in part responsible for the fact that after 1979, Jack did not submit any papers for peer-reviewed publication for years.

One of the final peer-reviewed publications by Jack, which appeared in 1980 in the *Journal of Herpetology*, was an ideal

starting point for the early career of one of us (BKS), as it was a careful analysis of the influence of temperature on call variation in the Arizona Toad (*Bufo microscaphus*). Over the next decade as the literature on anuran call variation in relation to sexual selection exploded, literally hundreds of papers would be published on how female frogs and toads select their mates on the basis of variation in call attributes, which were known to be influenced by size and temperature. Many of these contributions were inherently limited because of a lack of detailed analysis of temperature effects—something Jack's contribution clearly addressed. Papers were circulating with untested assumptions of strong relationships between male size and call variables, and those same variables and temperature. Jack's fine attention to detail during data collection impressed his students dramatically. It was because of his insistence that his students understand call variation at the most basic level that one of us (BKS) was able to submit a critique of a widely read publication within a day of its reception. The requisite data were "on hand;" data that showed that the assumptions of size and temperature effects in a bufonid in that manuscript were unfounded. The data for the critique existed solely because Jack required they be available to verify "you're doing it right."

PHOTO BY SANDRA LEANDER

FIG. 3. Max Nickerson and Jack Fouquette, 2012, ASU campus; Max, who received his PhD from ASU in 1970, is holding the award he received as a distinguished alumnus of ASU, awarded by the School of Life Sciences, and presented by Jack, a member of Max's dissertation committee.

The changing job market for field biologists in general, and herpetologists in particular, was a source of worry for Jack beginning in the late 1970s and early 1980s; like his parents decades before, he became concerned about the career opportunities for his students.

"*…hence I learned, at a very young age, that if you hankered for a career as a field biologist you were liable to starve to death.*"
—John Nichols

Jack often described how fortunate he was to have only had to compete with a handful of applicants for the position at Arizona State University in 1965. He knew that he was lucky to have been on the job market in herpetology when positions were relatively common—consequently, he was especially sympathetic to the plight of his graduate students, some of whom applied for dozens of positions prior to receiving even an interview. Some of his students left the academic career path in the 1980s and 1990s as a direct result of the reduction in job opportunities. Jack allowed his students great latitude in the projects they pursued, and he only coauthored manuscripts they published when it was truly a partnership—he knew it was critical they establish an independent record of scholarship.

Jack's horribly (like that of some "hoarders") cluttered office was legendary, as noted by all of his students. The quantity of materials therein reflected the breadth of his interests, which spanned all of herpetology, including snakes (Fouquette and Potter 1961), lizards (Fouquette 1968d; Mitchell and Fouquette 1978), and communities (Fouquette and Delahoussaye 1966; Fouquette and Lindsay 1955). When one of us (BKS) was preparing to depart for Jack's old stomping grounds, Austin, I had an educational experience in Jack's office thanks to having mustered the courage to ask for the return of a pamphlet loaned to Jack precisely four years prior. Fully expecting it was lost for good, and that the request for its return would only embarrass him, it was truly shocking to find that before the item had been fully described, Jack rose, and in as straight a line as could be achieved among the piles of paper leaning this way and that, walked to one towering collection, and from roughly 3 feet off the ground, one third from the top, deftly selected the edge of an item, and in a flurry similar to magician with a tablecloth, extracted it, steadied the remainder with the other hand, handed the pamphlet off all in one motion while returning to his seat with the comment, "Oh...I'd hoped to read that by now."

The great variation in the nature of species boundaries among anuran amphibians interested Jack throughout his professional career. He could recall in detail zones of intergradation and hybridization among dozens of North American bufonids, in part as a result of his association with the Blair lab during the heyday of investigations of species status in the genus *Bufo*. Even though he was "an old timer," he openly embraced new developments in systematics, including cladistics and the rise of the evolutionary species concept. Jack joined the newly formed Willi Hennig Society early. Though he came of age when the subspecies concept was dominant, he often confided that colleagues had "gotten it all wrong" when various forms had been subsumed as subspecies. Nonetheless, he never was one to be outspoken about such "mistakes" and never embarrassed students or colleagues in this respect. The Arizona Treefrog was one of his favorite examples. He was especially happy that one of his academic "grandchildren" (Erik Gergus, a PhD student of BKS and Jack) took on the issue and settled it convincingly, allowing the Arizona Treefrog (*Hyla wrightorum*) to be recognized by one and all as a species (and not a subspecies of *H. eximia*). His urgings led to a number of publications on elevation of subspecies to species, long before Joe Collins argued as much over twenty years ago. By contrast, Jack's last contribution, a "resurrection" of Schmidt's 1953 checklist (Schmidt 1953), coauthored with A. Dubois (Fouquette and Dubois 2014), has been reviewed somewhat less than favorably, both on the pages of this journal (Lannoo 2014) and elsewhere (Hillis 2015). The reviewers of Jack's final contribution, a self-published book, in part were sympathetic to his taxonomic conservatism, but overall, the book's reception has been, at best, lukewarm, largely as result of Jack's inconsistency in his self-avowed commitment to taxonomic stability at higher levels.

One of the oddities of life as an academic scientist is that you can be "adopted" into a family; you can become part of a lineage

by developing a relationship with a faculty member. Jack's major professor, Frank Blair, was an amazingly productive biologist, supervising 49 Ph.D. and 51 M.A. degrees between 1968 and 1982, and as a result was invited to lecture at more than 90 venues worldwide during the same span. As Jack's major professor, he can be viewed as our academic grandfather. Our simultaneous tenure at UT Austin in the mid-1980s was a return to our family roots, after a fashion. The days of large laboratories in which major professors in herpetology have many graduate students throughout their lifetimes are over (Sullivan 2014); nonetheless, Jack was an ideal mentor for those who were lucky enough to have him. When one of us (BKS) established an informal meeting in the Phoenix area in the early 1980s, "herp group" (inspired by, and named for a similar program organized by David and Marvalee Wake at UC Berkeley), the other (JEP) was the first speaker given he happened to be on a trip through his old stomping grounds some half dozen years after he obtained his PhD. Jack Fouquette was the most consistent participant at dozens of Phoenix Area Herp Groups over the next three decades. During his last Herp Group, Jack thoroughly entertained one and all with photographs he'd taken at the last World Congress of Herpetology in Canada in 2012. Jack used the photographs to administer a "herpetologists, then and now" quiz to all that arrived that evening.

Jack loved talking science, and he loved talking about scientists (Fig. 3), though he never said a bad word about anyone—more than one person referred to Jack as the "nicest man I ever met" or "the kindest person, ever," a real rarity for the scientific community. We doubt that there has ever been a more soft-spoken herpetologist than Jack Fouquette. His mild-mannered demeanor was as much his trademark as the rough-as-bark persona of Chuck Lowe was his (Rosen 2004). As different as these two Arizona herpetologists might have been, it is arguable that they both left their marks on herpetology at least in part through the students that they left behind. It might be that his gentle nature prevented Jack from serving as a hard-nosed, strict disciplinarian that could mold and shape students to his wishes. Instead, Jack was one to let students have a free rein, and to influence their growth and development with nuance and subtlety. It was this difficult-to-articulate characteristic that set Jack apart from others, that allowed students and some faculty members at ASU to look with envy at Jack and his relationships with his productive students. We knew we were special. We knew we had something that no one else in the department had: we had a major professor we could count on absolutely, one that was always available to us, come what may, one that would literally open his house to us if personal issues might have made it necessary, even if it meant supporting us for months at a time. It was time that Jack was always ready and willing to provide us. Jack finally had no more time to give on 28 August 2014.

Acknowledgments.—We thank John Alcock and Jim Collins for comments on the manuscript. Dave Cannatella and Travis La Duc, both of Jack's alma mater, UT Austin, were especially helpful in tracking down information on Blair. Max and Cheryl Nickerson, Sandy Leander, Barb Markley, and J. P. Collins, Sun Devils past and present, assisted in a number of ways. Ralph Axtell and Dave Hillis shared a number of experiences with Jack, which we deeply appreciate. R. Bowker, A. Holycross, J. Mitchell, and L. Vitt, all former students of Jack, were also helpful in the development of this contribution. Two of Jack's children, Dave Fouquette and Mari Firago, kindly provided access to Jack's personal materials.

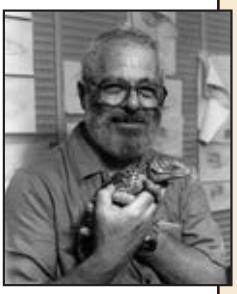
ERRATA—



In the Geographic Distribution note by Costa-Campos and Freire concerning *Scinax trilineatus* (2014, volume 45, number 3, p. 459), the second author's name should read Eliza M. X. Freire.

In the Natural History Note by Beaman and Tucker (2014, volume 45, number 3, p. 514, the lat/long coordinates listed are incorrect. The correct coordinates are 38.6459°N, 121.29842°W.

AWARDS FOR STUDENT* ATTENDANCE AT SSAR MEETING (UNIVERSITY OF KANSAS, 2015)

The *Carl Gans Collections and Charitable Fund* (hereafter the "Gans Fund") is pleased to announce that it will support two kinds of awards to students*—both graduate and undergraduate, but not postdoctoral—who are attending the SSAR meeting at the University of Kansas next summer (July 30 to August 3, 2015; for a description of this meeting see page 751 in this issue). There will be 20 awards covering the full student registration fee of US$150 and limited funds to support student travel expenses. Both awards are *open to all students* regardless of nationality*. **The deadline for receipt of applications for both awards is February 15, 2015**.

To be eligible, applicants (1) must certify their student status with a separate message from their professor; (2) must list the herpetological society or societies to which they belong*; (3) must be presenting papers (oral or poster) at the meeting; and (4) the paper's subject area must be within the broad spectrum of research conducted by Professor Gans on the biology of amphibians and reptiles (especially morphology, systematics, faunistics, behavior, physiology, and evolution). Applicants must provide a paragraph (no more than 300 words) describing the work to be presented at the meeting, to enable the selection process. *Award announcements will be made about March 15, 2015*, allowing all applicants to know their status before meeting registrations begin.

• **REGISTRATION AWARDS**. Selections will be made by SSAR. The application, research paper description, and certifications should be sent by email to: Dr. Marion Preest, SSAR Secretary, at mpreest@kecksci.claremont.edu (if by air mail, to her at: Joint Science Department, The Claremont Colleges, Claremont, CA 91711, USA). The award funds will be sent by SSAR directly to the University of Kansas, which will receive a list of the successful applicants.

• **TRAVEL AWARDS**: Selections will be made by the Gans Fund, on the recommendation of its Scientific Advisory Board. The Board consists of: Kraig Adler, Cornell University (USA), Aaron Bauer, Villanova University (USA), Amos Bouskila, Ben Gurion University (Israel), Herbert Rosenberg, University of Calgary (Canada), Linda Trueb, University of Kansas (USA).

A limited number of travel awards will be made. The maximum award for applicants from the USA and Canada is US$500; for all other countries $1000. The application, research paper description, and certifications should be sent to the Gans Fund; application details may be found at: http://www.carlgans.org (click on "Grants" in top menu bar). Submissions will be made via the web. Applicants should detail their expected expenses for the meeting including the travel costs; be sure to indicate the amount you are requesting from the Gans Fund and the amounts received (or applied for) from other sources. The award funds will be distributed by SSAR directly to the successful applicants. Further details may be obtained from the Gans Fund at the on-line address given above.

* For this meeting of SSAR, the meeting organizers have defined "student" as all student members of SSAR, HL, and ASIH, as well as student members of all national and international herpetological societies, who will be allowed to register at the "student member" rate of US$150.

Third Update!

UNIVERSITY OF KANSAS SSAR MEETING

THURSDAY, JULY 30 – MONDAY, AUGUST 3, 2015

Society for the Study of Amphibians and Reptiles

co-sponsored by Partners in Amphibian and Reptile Conservation (PARC)

together with the herpetological societies of Kansas, Missouri, and Arkansas, the Center for North American Herpetology, *and the* International Society for the History and Bibliography of Herpetology

Plenary Update: additional feature presentation by Harry Greene: *"The Life and Times of a KU Herpetology Icon: Henry Fitch and 70 Years of Snake Ecology"*

Set just a few miles from where he conducted seven decades of landmark research in community dynamics of Kansas snakes, this special SSAR event will review the monumental contributions of Henry Fitch, the *undisputed Father of Snake Ecology.*

Additional special activities conceived to honor the contributions of Henry Fitch include a block of talks on snake ecology (to be moderated by Harry Greene) and tours of KU's Fitch Reserve, site of his classic long-term snake ecology work (to be guided by George Pisani).

SSAR will hold its 2015 meeting on the beautiful and centrally-located campus of the University of Kansas. All scientific sessions will be held in the Kansas Union, which is adjacent to the KU Museum of Natural History, the setting of more than a century of research and graduate education in herpetology. The intimate campus setting will facilitate personal and friendly interactions while moderating fees for registration and lodging.

This unique campus format meeting will include oral and poster presentations, silent and live auctions, vendor displays, student social, symposia, and special lectures provided by **David Hillis** (Keynote) and **Miguel Vences** (President's Travelogue). SSAR will resurrect popular activities from the past, including:

- Redesigned audiovisual shows arranged by David Dennis and Eric Juterbock.
- Reception honoring distinguished senior herpetologists, allowing students to interact personally with luminaries in the field.
- Herpetological Quiz, arranged by the graduate students at UT Arlington and KU, with prizes for winners.
- Live Kansas amphibians and reptiles (organized by KHS), with photographic set-ups for use by delegates.
- Guided tours of the newly renovated Biodiversity Institute.

PROJECTED COSTS FOR KU MEETING

■ *Registration fees (member rates):*

Students $150
Regular $295
Seniors, retired / over 70 . . . . . $150

■ *Dorm room rates (on campus, linens included):*

Dual-occupancy rooms or suites, per day . . . . . .starting at $35
Single-occupancy rooms or suites, per day . . . . . starting at $55

There are many motels near campus. Motels allow more persons per room, at lower per-person costs (as low as $25/person). Full details will be included in the *Registration Announcement,* to be posted in Spring 2015.

Symposia Updates: *Finalized Participants*

Bones, Frogs, & Evolution

Organized by David Blackburn, Anne Maglia, and David Cannatella

This event will celebrate the exceptionally productive 40 years of scholarship of Linda Trueb and will include presentations by Ana Maria Baez, David Blackburn, David Cannatella, Luis Coloma, Eli Greenbaum, Juan Guayasamin, Anne Maglia, Dave McLeod, Greg Pregill, Chris Sheil, Helio de Silva, Erik Wild, and Marvalee Wake. Introduction by Leonard Krishtalka and Summary by William Duellman.

Frontiers in Integrative Organismal Biology: Herpetological Horizons

Organized by Rich Glor and Rafe Brown

This event will bring together a group of exceptionally research-active herpetologists working at the forefront of evolution-related fields, using amphibians and reptiles as study systems. Topics include speciation, adaptive radiation, convergence, phenotypic evolution, and the evolution of development—all through the lens of genomic approaches to understanding evolution of amphibians and reptiles. Participants include Frank Burbrink, Todd Castoe, Ben Evans, Matt Fujita, Luke Harmon, Ryan Kerney, Adam Leaché, Emily Lemmon, Jim McGuire, Rachael Mueller, Dan Rabosky, Erica Rosenblum, Robert Thompson, John Wiens, and Kelly Zamudio. Summary by David Wake.

Awards for student attendance at the University of Kansas meeting are being offered by the Carl Gans Fund. See page 750 for details and definition of "student."

Field Herpetology of the Southwest

Southwestern Research Station — 24 July–2 August, 2015

This 9-day course will introduce participants to an outstanding diversity of amphibians and reptiles of Arizona's Chiricahua Mountains and surrounding deserts.

Labs and lectures will focus on identification and ecology of herps. The majority of time will be spent in the field, hiking through low and high elevation habitat.

For more information about the course, contact Dawn Wilson. Ph: 520-558-2396; email: dwilson@amnh.org; http://research.amnh.org/swrs/herpetology-field-course

INFORMATION FOR CONTRIBUTORS

Herpetological Review is a peer-reviewed quarterly that publishes, in English, articles and notes concerning the study of amphibians and reptiles, as well as book reviews, commentaries, regional and international herpetological society news, and letters from readers directed to the field of herpetology. Articles reporting the results of experimental research, descriptions of new taxa, or taxonomic revisions are not published in ***HR***, but should be submitted to the ***Journal of Herpetology*** (for information, please refer to: http://www.ssarherps.org/pages/JHinstr.php). To submit a manuscript to ***HR***, please consult the SSAR webpage at:

<http://www.ssarherps.org/pages/HRinfo.php>

REPRINTS AND PAGE PROOFS

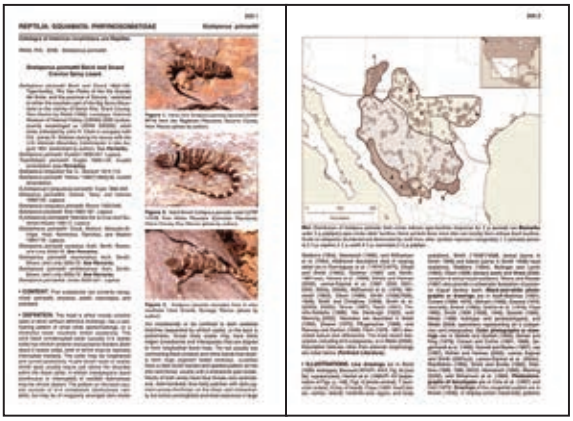
Page proofs are sent electronically to authors of all articles, book reviews, and obituaries, but are not prepared for natural history, geographic distribution, or herpetoculture notes. Proofs are sent as pdf files approximately 2–4 weeks prior to publication. High resolution electronic (pdf) reprints of notes, articles, book reviews, and obituaries are provided at no charge to the primary/corresponding author as a benefit of SSAR membership. Reprint files will normally be sent prior to the issue mailing date from the printer. Authors who are not current SSAR members may purchase pdf reprints from the SSAR Publications Office.

ADVERTISING

Herpetological Review accepts commercial advertising. Rates and copy information are available from the SSAR web page (http://www.ssarherps.org/pages/HRinfo.php).

Herpetological Review (ISSN: 0018-084X) is published quarterly (March, June, September, and December) by the Society for the Study of Amphibians and Reptiles at the Department of Natural Sciences, Williams Baptist College, P.O. Box 3692, Walnut Ridge, AR 72476, USA. Periodicals postage paid at Walnut Ridge, AR 72476 and at additional mailing offices.

All rights reserved. No part of this periodical may be reproduced without written permission of the Editor, except that authors and their agents are permitted to reproduce and distribute their own articles and notes.



POSTMASTER: Send address changes to Breck Bartholomew, SSAR Publications Secretary, P.O. Box 58517, Salt Lake City, UT 84158. **MISSING OR DAMAGED ISSUE?** Please notify Breck Bartholomew, SSAR Publications Secretary (e-mail: ssar@herplit.com) for a replacement.

SSAR PUBLICATIONS

SSAR publishes seven different series: *Journal of Herpetology, Herpetological Review, Facsimile Reprints in Herpetology, Contributions to Herpetology, Herpetological Circulars, Herpetological Conservation*, and the *Catalogue of American Amphibians and Reptiles* (see below for CAAR details). SSAR members receive prepublication discounts on all *Facsimiles* and *Circulars* and on volumes in the *Contributions* and *Herpetological Conservation* series. A complete pricelist of Society publications is available at: http://www.ssarbooks.com/.

CATALOGUE OF AMERICAN AMPHIBIANS AND REPTILES

The *Catalogue* consists of individual accounts of species and genera prepared by specialists, including synonymy, definition, distribution map, and comprehensive list of literature for each taxon. The accounts cover amphibians and reptiles of the entire Western Hemisphere. As of 2014, SSAR is making all CAAR accounts OPEN ACCESS as a service to the herpetological community. To access individual accounts, visit http://www.ssarcaar.com.

SOCIETY FOR THE STUDY OF AMPHIBIANS AND REPTILES

www.ssarherps.org

The Society for the Study of Amphibians and Reptiles, the largest international herpetological society, is a not-for-profit organization established to advance research, conservation, and education concerning amphibians and reptiles. Founded in 1958, SSAR is widely recognized today as having the most diverse society-sponsored program of services and publications for herpetologists. Membership is open to anyone with an interest in herpetology—professionals and serious amateurs alike—who wish to join with us to advance the goals of the Society.

All members of the SSAR are entitled to vote by mail ballot for Society officers, which allows overseas members to participate in determining the Society's activities; also, many international members attend the annual meetings and serve on editorial boards and committees.

All members and institutions receive the Society's primary technical publication, the *Journal of Herpetology*, and its bulletin, *Herpetological Review*; both are published four times per year. Members also receive pre-publication discounts on other Society publications, which are advertised in *Herpetological Review*.

To join SSAR or to renew your membership, please visit the secure online ZenScientist website via this link:

Ontogeny of Color Pattern in *Aspidoscelis tigris punctilinealis* (Dickerson), Sonoran Tiger Whiptail, in Central Arizona

Aspidoscelis tigris (Tiger Whiptail) is an abundant and widely distributed ground-dwelling heliothermic lizard in deserts and adjacent arid lands in the western United States and northwestern Mexico. The species and/or its derivatives have also colonized islands situated east and west of the Peninsula of Baja California (Walker et al. 1966; Walker and Maslin 1969, 1981; Wright 1993; Grismer 2002). Extensive geographic variation in scutellation, color pattern, and body size is present in the species and several continental and insular subspecies are recognized (Taylor and Walker 1991, 1996; Dessauer et al. 2000). Based on Dessauer et al. (2000), Taylor (1990), and Taylor and Walker (1996), three subspecies of *A. tigris* occur in Arizona: *A. t. punctilinealis*; *A. t. septentrionalis*; and *A. t. tigris* (see map in Dessauer et al. 2000). The geographic range of *A. t. punctilinealis* (= *Cnemidophorus tigris gracilis*; Taylor and Walker 1991, 1996; Reeder et al. 2002) also extends through the Mexican state of Sonora to the type locality on the largest of all Mexican islands, Isla Tiburón (~1200 km^2), Gulf of California, Sonora. Southeastward, it is distributed from Cochise Co., Arizona, into Hidalgo Co., New Mexico, where the only known zones of hybridization (= secondary intergradation) occur between *A. t. punctilinealis* from the west and the taxon from the east variously treated as either *A. t. marmorata* (= *C. t. marmoratus*; Dessauer and Cole 1991; Dessauer et al. 2000) or *A. m. marmorata* (= *C. m. marmoratus*; Hendricks and Dixon 1986).

Sonoran Tiger Whiptail (*A. t. punctilinealis*), diagnosed primarily on the basis of color pattern characters, in desert flat communities has been the focus of several detailed studies pertaining to genetics (Dessauer and Cole 1991; Dessauer et al. 2000), meristic variation (Walker et al. 1966; Taylor 1990; Taylor and Walker 1991; Dessauer et al. 2000), and taxonomy (Walker et al. 1966; Taylor and Walker 1996; Dessauer et al. 2000). Nevertheless, these studies have left substantial gaps in our knowledge of ecology, body size variation, and ontogenetic development of color pattern in the widely distributed and ubiquitous *A. t. punctilinealis*. For example, those who picture Sonoran Tiger Whiptail as a mottled or spotted lizard with stripe fragments dorsally and a black throat and chest ventrally, as described by Dessauer et al. (2000) and Taylor (1990) using specimens in the size range of adults, would find that young-of-year (YOY) individuals have completely different dorsal and ventral patterns that are intriguing exceptions to that image. We infer that such drastic ontogenetic variation in color pattern in *A. t. punctilinealis* is of some unknown adaptive significance to YOY and adults, rather than the mere results of developmental processes. Thus, we conducted this field and laboratory investigation to obtain data pertaining to the complexities of individual and ontogenetic variation in color pattern which were not listed as objectives in other studies of the subspecies (e.g., Walker et al. 1966; Taylor 1990; Taylor and Walker 1991; Dessauer et al. 2000).

Materials and methods.—We assessed life coloration in YOY individuals either collected or photographed by BKS in 2012 and 2013 in the vicinities of Phoenix, Maricopa Co., and Payson, Gila Co., central Arizona, to describe the juvenile pattern of *A. t. punctilinealis* (Fig. 1; Appendix 1). We also obtained digital photographs of the dorsum and ventrum of a juvenile of *A. t. punctilinealis* from Isla Tiburón, Sonora, Mexico, in the California Academy of Sciences (CAS; Appendix 1). We used a sample of 28 specimens collected by BKS and associates in May and June 2006 from Gila Co., Arizona, to assess and describe individual and ontogenetic variation in adults of *A. t. punctilinealis* (Fig. 2; Table 1; Appendix 1). This sample was also used to determine the mean and range of variation of granular scales between the paravertebral stripes at midbody (PV) and the mean and range of variation in percentage of the granular scales around midbody located between the paravertebral stripes (PV/GAB). A sample of *A. t. punctilinealis* (Fig. 3; Appendix 1) collected from in Maricopa Co. 50 km SW of Phoenix was photographed for comparison with specimens from Gila Co. in the vicinity of Payson (Fig. 4). We used calipers to measure the SVL of each preserved specimen of Sonoran Tiger Whiptail to the nearest mm, some of which were also measured prior to preservation.

Results.—Throughout the vast binational range of *A. t. punctilinealis* gradual ontogenetic changes occur throughout the life cycle (~38 mm to >106 mm) to strikingly transform most aspects of both the dorsal and ventral color pattern components seen in YOY to the different pattern ensembles seen in adult males and females (Figs. 1–3). However, two aspects of the dorsal pattern and scalation are not subject to ontogenetic variation; the number of granular scales (i.e., spacing) between the paravertebral

FIG. 1. Young-of-year *Aspidoscelis tigris punctilinealis*. Top and center: vicinity of Phoenix, Maricopa County, Arizona (SVL = 38 mm [lateral stripes present], 30 June 2012 and SVL = 50 mm [lateral stripes absent], 7 July 2013, respectively). Bottom: vicinity of Payson, Gila County Arizona (SVL = 42 mm [lateral stripes present], 30 July 2013).

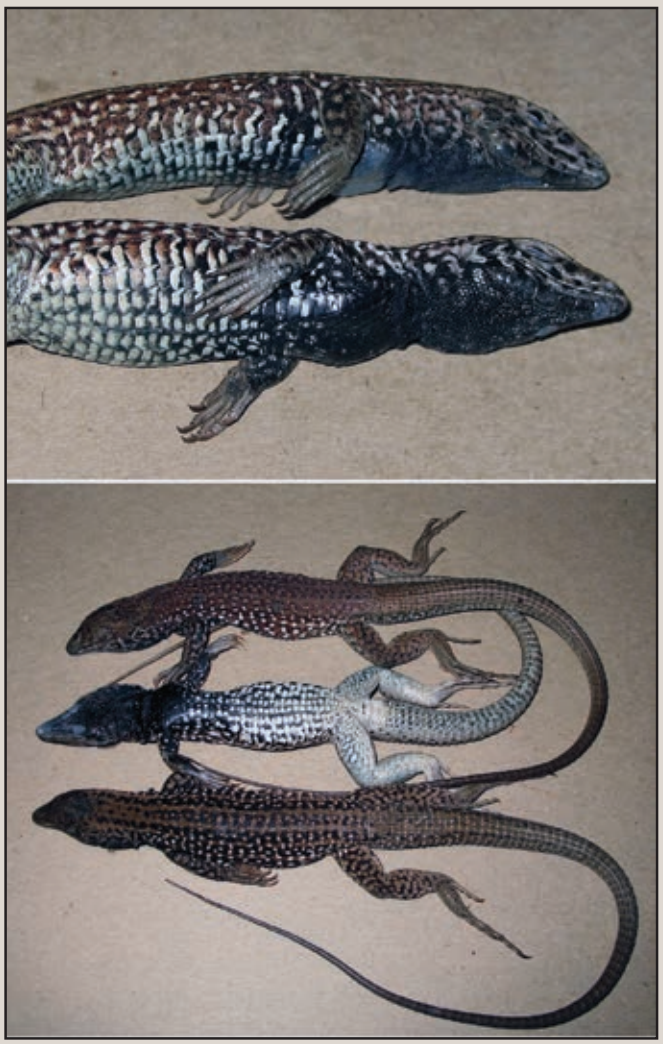

FIG. 2. Adults of *Aspidoscelis tigris punctilinealis* from vicinity of Payson, Gila County, Arizona (elevation = 1600 m), showing variation in dorsal and ventral color patterns (top = 26 May 2006; bottom = 27 May 2006).

stripes at midbody (PV = 7.6 ± SE 0.27, range 5–12, N = 28) and percentage of the granular scales around midbody located between the paravertebral stripes at midbody (PV/GAB = 8.7 ± 0.26, range 6.0–12.0, N = 28). The narrow spacing of the paravertebrals, the dorsal-most pair of pale longitudinal stripes, in all except specimen BKS 1841 with a PV count of 12, is correlated with the absence of a middorsal vertebral stripe.

Consistently present in the dorsal pattern of YOY of *A. t. punctilinealis*, based on individuals collected from Isla Tiburón (March–August 1964, 1967), vicinity of Phoenix (June–July 2012, 2013), and vicinity of Payson (July–August 2013) are white to gray to tan components on the body and limbs set within a brown-black to black ground color. Typically, such juveniles have six vivid pale-colored longitudinal primary stripes (i.e., three on each side of body; Fig. 1), numerous distinct spots of variable shapes in the lower aspect of each side of the body, and incipient (i.e., developing) short bars arranged perpendicularly to the stripes. Also present are elongate gray-white vermiculations of variable shapes on the fore and hind limbs.

The three stripes (ventral to dorsal) described from the right side of the body, and mirrored on the left, of a captured/released YOY from Payson (e.g., the individual of 42 mm SVL in Fig. 1) include: 1) the lateral extending from posterior to the ear opening to the hind limb then posteriorly from it along the side of the anterior third of the tail (the part of the stripe on the trunk is gray-white, very irregularly margined with constrictions, interruptions, and vertical extensions into the intervening fields); 2) the dorsolateral extending from the superciliary scales on the right lateral aspect of the head that continues onto the anterior third of the tail (the part on the trunk is gray-white, moderately irregularly margined with no interruptions); and 3) the paravertebral extending from a parietal scale on the posterior part of the head to the base of tail then onto the tail as a linear series of spots

TABLE 1. Categories of striping patterns in female and male specimens of *Aspidoscelis tigris punctilinealis* from Gila County, Arizona, collected by Brian K. Sullivan (BKS). SV = stripes visible (0 = all primary stripes + vertebral (V) are visible); SD = stripes disrupted: 2 = laterals are disrupted; 4 = laterals and dorsolaterals are disrupted; 6 = laterals, dorsolaterals, and paravertebrals are disrupted.

BKS collection number (N)	Sex and SVL mm (N)	SV	SD
1841 (1)	84 (1)	6 + V	0
1800, 02, 14, 15 (4)	69, 76, 75, 73 (4)	4	2
1837 (1)	88 (1)	2	4
1799, 1801, 03, 10-13, 16, 18, 36, 38, 39, 40 (13)	68. 79, 82, 95, 75, 76, 83, 62, 95, 94, 101, 82, 81 (13)	4	2
1804, 17, 19, 20, 21, 22 (6)	92. 97, 87, 99, 94, 106 (6)	2	4
1805, 09, 35 (3)	91, 96, 100 (3)	0	6

FIG. 3. Adults of *Aspidoscelis tigris punctilinealis* from 50 km southwest of Phoenix = W of Mobile on SR 238 at mile marker 24 (elevation = 350 m), Maricopa County, Arizona, showing variation in dorsal and ventral color patterns (top and bottom, same individuals, from 14 August 2006).

(the part on the trunk is gray-white, only slightly unevenly margined, and has no interruptions). One adult female (BKS 1841; 84 mm SVL) from near Payson has six primary stripes and an unevenly margined vertebral stripe indicating that an occasional YOY of *A. t. punctilinealis* has seven stripes all of which persist into adulthood.

In *A. t. punctilinealis*, the longitudinal areas of dark ground color between the light hued stripes on both sides of the trunk constitute the fields, here described on the right side of the same YOY from Payson. The fields include: 1) a brown-black lower lateral (located ventral to lateral stripe) with a linear array of >20 distinct gray-white spots and incipient vertical bars; 2) a black upper lateral (located dorsal to lateral stripe) with a linear series of 21–22 distinct isolated gray-white spots; 3) a black dorsolateral (located dorsal to dorsolateral stripe) with no evidence of spots; and 4) the right half of the middorsal (between the paravertebral stripes) with no evidence of either spots or a vertebral stripe (Fig. 1). The forelimbs are black with a profusion of gray-white spots and vermiculations. The hindlimbs are black with gray-white streaks, vermiculations, and spots. The head is dark brown with some scales having black edges. The tail is striped anteriorly, becoming a distinctive hue of blue posteriorly. Ventrally the Payson juvenile is mostly gray-white, though some dusky gray-black is evident in the anterior thoracic region.

Comparisons of Phoenix YOY with the description of Payson YOY revealed subtle differences. An individual from Phoenix of 38 mm SVL (Fig. 1) and based on the right side has a straighter and essentially continuous lateral stripe, a paravertebral continuously extending onto the anterior third of the tail, and a lower lateral field marked by an essentially linear series of spots. A slightly larger lizard from Phoenix (50 mm SVL in Fig. 1) was photographed *in situ* from the left side. It differs from the preceding ones from Payson and Phoenix in having no evidence of either a lateral stripe or of the fragments thereof and, thus, no subdivision of lateral ground color into upper and lower lateral fields, though present is a profusion of variable gray-white spots and vermiculations ventral to the dorsolateral stripe. Moreover, this lizard lacks a hue of blue on the posterior part of tail. Two YOY individuals photographed by BKS 10 August 2013 from Phoenix, one of ~42 and one of ~55 mm SVL, have yet additional pattern components including developing spots in the dorsolateral fields and a vertebral stripe to near the forelimbs followed by an alignment of "stripe fragments" more posteriorly, pattern components not apparent in the three YOY previously described. A YOY from Isla Tiburón (CAS 104460) closely resembled six-striped juveniles of the subspecies from Phoenix.

The color patterns in adults of *A. t. punctilinealis* from the vicinity of Payson (Fig. 2; Table 1), and those from the Phoenix area (Fig. 3) ~111 km to the southwest, differ based on individual variation in the same size classes and the stage of ontogenetic development at the time of collection which are not strictly correlated with SVL in either of these areas. In all except one adult from Payson, the seven-striped female, the laterals if present in the juvenile pattern, have become disrupted by development of black ground color in the stripe configuration. However, the dorsolaterals have become disrupted in only seven (87–106 mm SVL; Table 1) and the paravertebrals are also disrupted in only

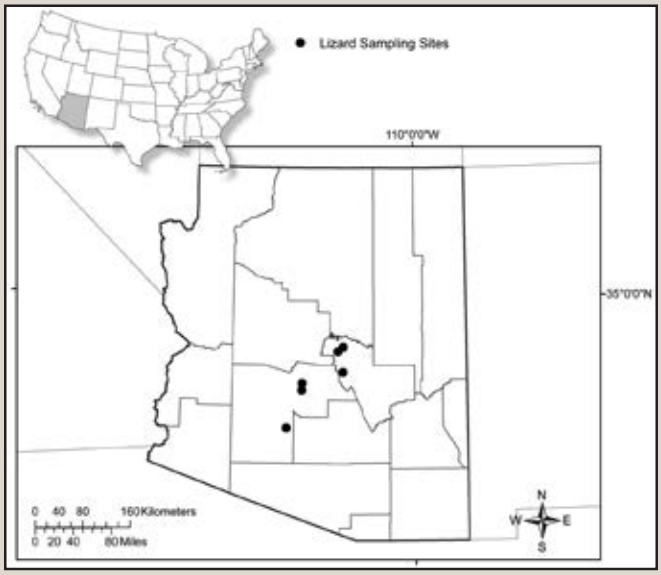

FIG. 4. Three sampling sites for *Aspidoscelis tigris punctilinealis* in Gila County (right) and three in Maricopa County (left), Arizona, referenced in this report.

three (91–100 mm SVL; Table 1). The typical mature dorsal pattern in this form, then, consists of a variable number of brown-tan stripes and stripe fragments, a profusion of gray-white spots of a variety of shapes which occur in all of the black fields and superimposed on stripes and stripe fragments, in addition to the spotted and vermiculated fore and hind limbs (Figs. 2–3; Table 1). The tail becomes brown-black without either evidence of stripes or distinct spots. The head becomes dark brown with scattered black spots. From a distance in the field, large adults of *A. t. punctilinealis* appear as brown-black lizards with gray-white spots. Ventrally, both males and females develop a darkly blotched to solid black throat, gular fold, and thoracic region, and a checker-board pattern of black and gray-white scales on the abdomen (Figs. 2–3). The ventral surfaces of the hind limbs and tail have dusky to black scales and blotches (Figs. 2–3).

Discussion.—Walker and Maslin (1969, 1981) found YOY color patterns and ontogenetic development important in the assessment of taxonomic boundaries, and potentially of adaptive significance, in other taxa of the *A. tigris* species group (sensu Walker and Maslin 1969). Ontogeny of color pattern was not included as an objective in previous studies of *A. t. punctilinealis*. Taylor (1990) analyzed *A. t. tigris* and *A. t. punctilinealis* in a contact zone in northwestern Arizona, but did not consider juvenile patterns because the characters of color pattern analyzed required lizards of adult sizes in the range of 74–101 mm SVL. Similarly, Dessauer et al. (2000) studied a hybrid zone between *A. t. punctilinealis* and *A. t. marmorata* (= *A. m. marmorata*) in Hidalgo Co., extreme southwestern New Mexico, using samples comprising lizards of 62–97 mm SVL. Herein, we used samples spanning ~38–106 mm SVL, with the largest preserved male examined having a record body length for *A. t. punctilinealis* (individuals measured by BKS prior to preservation exceeded 115 mm SVL).

Ontogenetic loss of some or all stripes is not uncommon among species of *Aspidoscelis* (Duellman and Zweifel 1962; Walker 1981a, b; Walker and Cordes 2011), but the adaptive significance of these color pattern changes remains problematic. Given that adults and juveniles of *A. t. punctilinealis* occupy the same habitats whether in the vicinities of Phoenix or Payson (Fig. 4), any adaptive value presumably relates to variation in behavior rather than habitat selection (BKS, unpubl.). The dorsal striped pattern of juvenile lizards may offer protective coloration in areas with grass cover and the broken light of shrubs, whereas the spots mixed with black and brown components in adults would provide a cryptic effect in more open areas dominated by rocks of various sizes and little vegetation. Also of unknown adaptive significance in *A. t. punctilinealis* is the extensive development of black pigment on the ventral surface of adults. North of Payson in Arizona, southern Utah, and southwestern Colorado, the subspecies is replaced by *A. t. septentrionalis* (Plateau Tiger Whiptail) which has a different striping pattern that includes supernumerary stripes and lacks an extensive ventral distribution of black pigment. However, ontogenetic changes in color pattern from hatchling through adulthood have not been assessed in *A. t. septentrionalis*.

Acknowledgments.—We thank Elizabeth, Justin, and Keith Sullivan for assistance in the field. Collecting permits were provided by the Arizona Game and Fish Department (2006–2013, to BKS), and collecting methods were approved as part of IACUC protocols (2006, 2009, and 2011) for surveying and vouchering lizards. Jens Vindum and Graham Noel of CAS kindly provided digital photographs of a YOY lizard from Isla Tiburón. We credit Jackson Shedd for the suggestion that shaped this contribution into an article, and the subsequent review offered by Harry L. Taylor materially improved its structure and content. We gratefully note that an anonymous reviewer suggested inclusion of the map. Finally, we thank Hanna Ford and Jackson Cothren, Center for Advanced Spatial Technologies, University of Arkansas, for creation of the map showing sites and counties from which lizards were collected and/or photographed.

Estimating Clutch Size Using Eggshell Fragments in Depredated *Macrochelys temminckii* Nests

Nest predation rates are extremely high in many freshwater turtle populations (Ewert 1979), which limits recruitment and makes it difficult to determine population production patterns. Mean clutch size is a critical component of demographic analyses of turtle populations because it is needed to determine annual fecundity (Congdon et al. 1993, 1994; Reed et al. 2002). Therefore, the ability to reliably estimate clutch size from depredated egg shell fragments could provide a more robust estimate of annual fecundity in turtle populations with very high nest predation rates than would estimates derived from intact nests alone.

In some cases it may be possible to estimate clutch sizes in depredated turtle nests by counting the number of egg shells found in and around the nest cavity. However, depredated egg shells may be crushed or shredded into numerous small fragments (Rearden 1951; Hernandez et al. 1997), and it can be very difficult and time consuming to piece individual eggs back together in order to estimate clutch size. As an alternative, we predicted that the total mass of shell fragments collected around depredated nests could be used to estimate clutch size. Turtle shells consist of an outer calcified layer and two fibrous shell membranes that collectively comprise an average 11–12% (range = 4–25%) of the total egg mass (Miller and Dinkelacker 2008). The contribution of the calcified and fibrous layers to the total mass of the egg shell varies substantially among species, but exhibits low variability within a species (Ewert 1979).

In an effort to reestablish an extirpated population in southern Oklahoma, USA, 249 adult *Macrochelys temminckii* were released in oxbow lakes at Tishomingo National Wildlife Refuge (TNWR) and surrounding Army Corps of Engineer land in 2007 (Moore et al. 2012). Nesting activity has been monitored every year following the release as part of a larger effort to gauge the success of the reintroduction. As is the case in many turtle populations, predation by raccoons was a major source of egg mortality (Moore et al. 2012; Miller and Ligon 2014). Because nest predation rates approached 100% when nests were not protected (Moore et al. 2012), direct determination of clutch sizes was not feasible. Therefore, we tested the efficacy of using eggshell fragments collected from depredated nests to estimate clutch sizes in this *M. temminckii* population.

Collection of shell fragments.—Shell fragments were obtained from intact nests of known size, depredated natural nests of unknown size, and depredated artificial nests of known size. The intact nests of known size were laid either by brood stock at the Tishomingo National Fish Hatchery (TFNH) or by

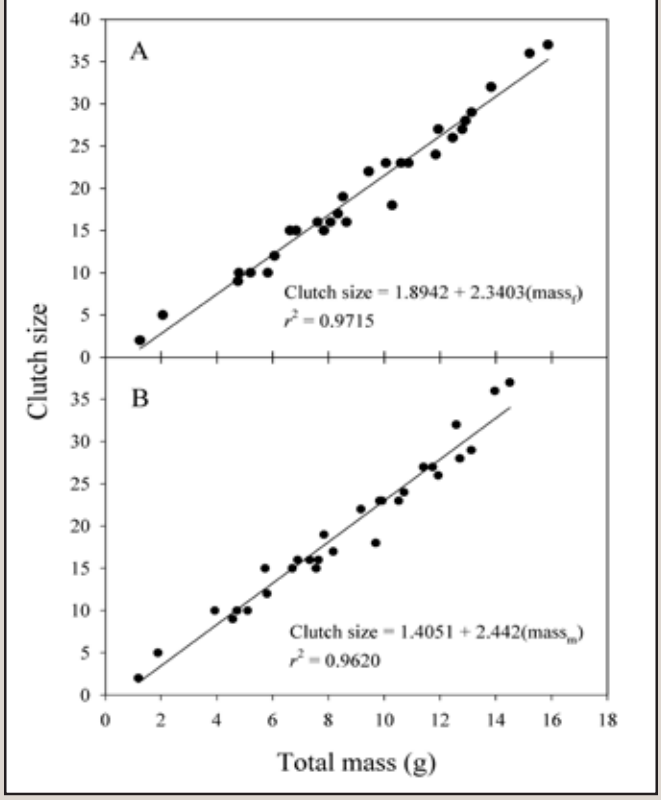

FIG. 1. Clutch size as a function of (A) dried shell fragment mass (mass$_f$) and (B) dried shell membrane mass (mass$_m$).

females released at TNWR in 2007. Reported clutch sizes for intact nests include only hatched eggs (not infertile eggs or eggs with embryos that failed to fully develop) because we used only shell fragments from eggs that hatched to construct our models. The depredated natural nests of unknown size were laid by females released at TNWR in 2007. The depredated artificial nests of known size were composed of inviable eggs laid by brood stock at TNFH and buried at TNWR as part of a separate nest predator study.

Nests laid at TNFH in the summers of 2010 and 2011 were excavated within a few hours of being constructed and the eggs were incubated at a constant temperature of 28.5°C in plastic containers filled with moist vermiculite (1:1 vermiculite:water by mass). We protected intact nests located at TNWR in the summer of 2010 with hardware cloth until the end of July, at which point we excavated the nests, with incubation completed at a constant temperature of 28.5°C as above at TNFH. We collected shell fragments from the plastic containers after the eggs had hatched. Intact nests located at TNWR in 2011 failed to produce hatchlings and were not included in the study.

When we located depredated natural nests at TNWR in 2010 and 2011, we searched within approximately 2 m of the nest cavity for shell fragments. In 2011, we obtained shell fragments collected from depredated artificial nests of varying clutch sizes (range 5–40). These nests were created at TNWR as part of a separate study designed to record raccoon behavior during predation events (Thompson 2013). The eggs that we used came from inviable clutches laid by captive females at TNFH. All shell fragments were stored in labeled plastic bags and frozen until they were processed.

Preparation of shell membranes.—Shell fragments were first rinsed to remove substrate and any remaining egg content. It was possible to reconstruct entire, or nearly entire, egg shells from shell fragments that were at least two-thirds intact. We estimated the percent missing for each reconstructed egg shell within a clutch and labeled it with a unique clutch and egg number combination. We put each reconstructed egg shell in a 50°C drying oven for 24 h and then recorded the mass of each (± 0.0001 g). This included the mass of the membrane and any of the remaining calcified layer, much of which flaked off prior to and during the drying process. Additional shell fragments that could not be assigned back to an individual egg shell within the clutch were dried and weighed together. We soaked each reconstructed egg shell and all additional shell fragments in 75 mL of 5% acetic acid for 24 h to remove the remaining calcified layer. We put each reconstructed egg shell and all additional shell fragments back in a 50°C drying oven for 24 h and then reweighed them. For each clutch, we added the masses of dried reconstructed egg shells and additional shell fragments to obtain the total mass of dried shell fragments for the entire clutch, both with and without residual calcium carbonate. Decalcified shell fragments will hereafter be referred to as shell membranes and those with the calcified layer as shell fragments.

In contrast to shell fragments collected from hatched eggs, most depredated shell fragments were too small to piece together. With the exception of four clutches, we processed depredated nests as an entire clutch instead of as individual eggs. After rinsing, the shell fragments from each depredated clutch were collectively dried, weighed, and soaked in 2 L of 5% acetic acid for 24 h. If calcium remained after 24 h, we placed the shell fragments in an additional 1.5 L of 5% acetic acid for another 24 h. After the calcified layer had dissolved, we dried and reweighed the shell membranes from the entire clutch.

Statistics.—We assessed the relationship between the total mass of shell fragments from intact nests and clutch size and the relationship between total mass of shell membranes from intact nests and clutch size using least-squares means linear regression. The resulting linear equations were then used to estimate clutch sizes of depredated nests. We did not include clutches of depredated artificial nests in our analysis but instead used them to validate the accuracy of our models. All analyses were performed using Sigma Plot 8.0.

Results.—We collected shell fragments from 29 intact clutches of known size, 16 depredated natural nests of unknown size, and 7 depredated artificial nests. Clutch size in the intact nests was 2–37 eggs. We reconstructed 531 eggs from the 29 intact clutches and 46 eggs from four of the depredated clutches. The mass of a reconstructed shell membrane averaged 0.4352 ± 0.0517 g (mean ± SD) and the mass of a reconstructed shell fragment averaged 0.5342 ± 0.2731 g.

Clutch size scaled positively and significantly to both total clutch shell fragment mass and shell membrane mass (Fig. 1). The resulting linear equations were:

$$\text{Clutch size} = 1.8942 + 2.3403 \times (\text{Fragment mass}) \quad \text{(eqn. 1)}$$
$$\text{Clutch size} = 1.4051 + 2.4420 \times (\text{Membrane mass}) \quad \text{(eqn. 2)}$$

Although shell fragments were expected to generate more variable results than membrane mass because of the varying amounts of calcium carbonate that remained adhered, using shell fragments produced a higher correlation coefficient with clutch size than did shell membranes (r^2 = 0.9715 and 0.9620,

TABLE 1. Actual and estimated clutch sizes of seven depredated artificial nests.

Mean			18.6

respectively). However, the difference between the two was very small, and the variability in mass among individual eggs was much greater before the shells were decalcified in acid.

Clutch sizes of depredated artificial nests were calculated using both shell fragments and shell membranes to evaluate the accuracy of each method (Table 1). Shell membranes generated values much closer to the known size of each clutch; therefore, eqn. 2 was used to estimate the clutch sizes in naturally occurring depredated nests at TNFH (Table 2). The mean estimated clutch size from these nests was 18.6 eggs (range 7–29).

Discussion.—Our results indicate that the total mass of shell membranes is a reasonable method for estimating clutch size in depredated *M. temminckii* nests. The regression model based on total membrane mass of eggs from depredated artificial nests generated clutch size estimates that were within one egg of actual clutch sizes. The mean estimated clutch size in depredated natural nests (18.6 eggs) is comparable to mean clutch size in 2010–2011 intact nests from the same population (22.4 eggs) and in the captive population at TNFH (25.5 eggs).

The regression equation calculated from shell fragments was similar to the regression equation calculated from shell membranes, but clutch size estimates using the mass of shell fragments greatly overestimated actual clutch size in depredated artificial nests. This likely resulted from differences in the way depredated shell fragments and hatched shell fragments were processed. Calcium flaked off of shell fragments (predated and hatched) to varying degrees after they were put in collection bags. The calcium that had flaked off of depredated shell fragments into the collection bag was included in the total mass of shell fragments. In contrast, the calcium left in the collection bag after all the hatched eggs were processed could not be added to the total mass of shell fragments for the entire hatched clutch because it was not possible to separate the calcium from the vermiculite that had adhered to the shell fragments after hatchlings had emerged. Therefore, the regression equation based on the total mass of shell fragments from hatched clutches was not a good predictor of clutch size in depredated nests. If the mass of calcium left in the collection bag had not been included in the total mass of shell fragments from depredated clutches, then the total mass of shell fragments may also have been a viable method for estimating clutch size. However, the standard deviation of the mass of a reconstructed shell fragment was an order of magnitude greater than the standard deviation of the mass of a reconstructed shell membrane, so models generated by the mass of shell fragments may still not be as accurate as those generated by the mass of shell membranes even when egg shells from depredated and intact nests are processed the same way.

Although the estimates produced for depredated artificial nests were quite accurate, estimated clutch sizes in depredated natural nests are likely underestimates of actual clutch sizes for two reasons. First, the individual who collected shell fragments from depredated artificial nests was the same individual who buried the eggs and she therefore knew how many shells fragments to look for around the nest cavity. If her hand counts while collecting eggs did not match the number of eggs that were buried, then she continued searching further from the nest until most of the shell fragments were found by her approximation. When collecting shell fragments from depredated natural nests, we did not know how many eggs the nest originally contained and we stopped searching for shell fragments approximately 2 m from the nest cavity. It is especially difficult to find shell fragments when nests are close to the water or there is a lot of leaf litter surrounding the nest. Second, predators may inadvertently consume some of the shell fragments or consume a portion of the eggs away from the nest cavity. Burke et al. (2009) found turtle shell fragments in raccoon scat and we observed the same in 2011.

This method of estimating clutch size in depredated nests is widely applicable to other turtle species and possibly other egg-laying amniotes that can experience high predation rates (e.g., lizards). A relatively large source of nests with known clutch sizes is needed to generate predictive models. We found very few intact *M. temminckii* nests, so we were able to build and test our models only because we had access to infertile eggs. However, assurance colonies are maintained for many turtle species and clutches may be readily available for similar analyses for these species.

Acknowledgments.—Funding was provided by a Faculty Research Grant to D. Ligon from the Missouri State University Graduate

College and by the Delta Foundation. Equipment was provided by J. D. Riedle, Missouri State University, and Tishomingo National Fish Hatchery. We thank M. B. East, E. C. Hollender, and B. M. Fillmore for assistance in the field and J. Heywood, B. Greene, and R. Pavlowsky for constructive criticism regarding our manuscript. We obtained approval for this project from the Missouri State University Animal Care and Use Committee (protocol 10015) and the Oklahoma Department of Wildlife Conservation (Scientific Collector's Permit #4871).

First Documented Use of Underpass Culverts by the Endangered Growling Grass Frog (*Litoria raniformis*) in Australia

Road ecology is now a significant branch of ecology aimed at quantifying the effects of roads and determining means of avoiding, minimizing and compensating for their negative impacts (van der Ree et al. 2011). Roads and other forms of linear infrastructure have long been recognized as having deleterious impacts on wildlife populations, primarily through collision-related mortality and habitat fragmentation (Forman and Alexander 1988; Spellerberg 1998; Trombulak and Frissell 2000; Forman et al. 2002). Amphibians seem to be particularly vulnerable to death on roads (Goldingay and Taylor 2006; Beebee 2013). Fauna crossing structures (overpasses and underpasses) are now being increasingly recommended and implemented in Europe, North America and Australia in particular to mitigate the impact of roads, with varying levels of success (Dodd et al. 2004; Beebee 2013).

Underpasses (e.g., bridge spans, culverts) are one such mitigation measure to facilitate the safe passage of amphibians under roads, often in combination with "funnel fencing" to guide animals to the underpass and to prevent access to the road. The majority of studies of the use of these structures by amphibians have been carried out on migratory species in the Northern Hemisphere (e.g., Langton 1989; Patrick et al. 2010; Beebee 2013). Relatively little attention has been paid to the effectiveness of underpasses for Australian species, which do not undertake mass overland migrations. Despite a general lack of empirical evidence that they are effective at facilitating movement across roads or ameliorating effects at the landscape or population level (van der Ree at al. 2011; Beebee 2013), underpasses are routinely incorporated into road design in Australia to facilitate the movement of amphibians and maintain habitat connectivity (van der Ree et al. 2007). Given this lack of data, it is important to document and monitor the use (or lack of use) of such structures by amphibians in Australia, particularly where they have been built with the specific aim of ameliorating effects of roads on threatened species.

One threatened Australian amphibian for which underpasses have been built is the Growling Grass Frog, *Litoria raniformis* (Fig. 1). *Litoria raniformis* is a large, semi-aquatic frog that grows to 100 mm SVL. It occurs in southeastern Australia, including Tasmania, where it is typically found in still or slow-moving freshwater habitats (Pyke 2002). The species declined markedly across its range late last century and it is now listed as "endangered" in Victoria (DSE 2013), "vulnerable" under the Commonwealth Environment Protection and Biodiversity Conservation Act 1999 (EPBC Act), and "endangered" in the IUCN 2012 Red List (Hero et al. 2012). The cause of the decline is poorly understood but it is believed a combination of factors are responsible including habitat loss, urbanization, introduced predators, and diseases such as chytridiomycosis (Mahony 1999; Pyke 2002; Heard et al. 2012).

Underpasses for *L. raniformis* have been incorporated into the design of dual and single carriageway roads around Melbourne, Victoria. Typically, the underpasses constructed are culvert-type

designs of various sizes and dimensions and are usually located at low-lying points in the landscape where they perform the additional role of facilitating drainage under the roadway. Despite the construction of numerous underpasses, some designed specifically for the species, it has never been shown conclusively that *L. raniformis* actually uses these structures, so their use as a mitigation measure for the loss of habitat connectivity for this species has been largely experimental (DEWHA 2009a, b; Heard et al. 2010). In this study, the construction of a wetland and underpass as a compensatory measure for the removal of habitat of a population of *L. raniformis* for residential development provided an opportunity to examine the use of underpass culverts by this species.

METHODS

Study area.—This study was undertaken in Wollert, a suburb on the northern outskirts of Melbourne, Victoria, Australia. The region has a temperate climate and experiences cool winters and warm to hot summers. The area is undergoing rapid urban growth associated with Melbourne's expanding population, which has resulted in a number of water bodies supporting *L. raniformis* populations being destroyed. One such site was a farm dam located within land earmarked for residential development, where a population of *L. raniformis* was discovered in 2002 (Costello et al. 2006). The proponent of the development was granted permission to destroy the dam under the provisions of the EPBC Act provided that, as an offset, a new wetland was constructed and the *L. raniformis* population translocated into it beforehand. The new wetland was constructed in 2009 and the dam was destroyed in 2011.

The replacement wetland, situated approximately 500 m SE of the dam, was constructed in the drainage line of Edgars Creek as part of a package of works completed for a two-lane, single carriageway municipal road crossing east to west over the creek. The wetland consists of two "ponds," one on either side of the road. Each pond has a water surface area of approximately 240 m^2. Both ponds have a maximum depth of approximately 1.5 m and are vegetated with emergent, submergent, and floating macrophytes to provide habitat for the translocated *L. raniformis* population. The ponds are connected under the road by four 2.4 m W × 1.2 m H × 20 m L concrete box culverts, situated approximately 1 m below the road pavement and set back under the road pavement by approximately 1.5 m to reduce culvert length and improve the aesthetics of the structure in an urban setting (Fig. 2). The bases of three of the four culverts are below the natural water level and hence are permanently inundated. This ensures the water level is maintained throughout and allows for water to move unimpeded along Edgars Creek during periods of high flow. The fourth culvert has been altered specifically to provide a dry crossing option for *L. raniformis*, although it too is likely to be briefly inundated during periods of high flows (Fig. 3). Four 12 × 12 mm galvanized mesh funnel fences (17 m L × 0.8 m H) were installed on each side of both ponds to restrict frogs from moving onto the road and to funnel frogs towards the culvert entrances. Additionally, a 100-m-wide fenced frog corridor was established to direct the movement of dispersing *L. raniformis* from the dam to the constructed wetland.

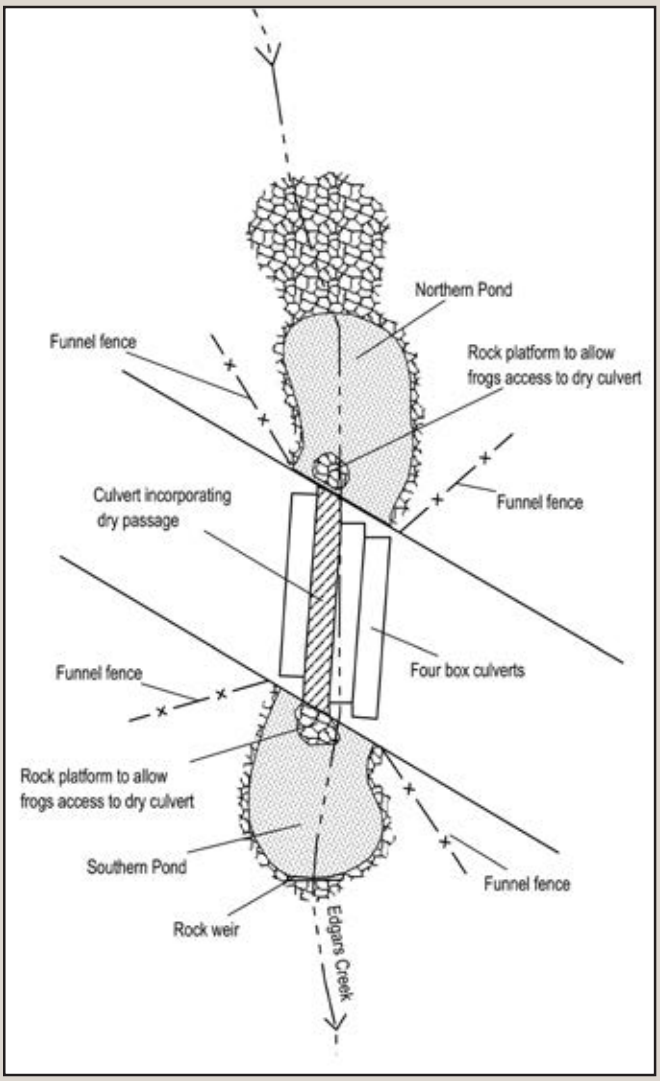

FIG. 2. Design features of the constructed wetland showing the underpass culverts (adapted from a plan produced by Spiire Pty Ltd).

Monitoring of the L. raniformis *population.*—Translocations of *L. raniformis* from the farm dam to the constructed wetland were conducted over five dates. During this period, the population was monitored to assess the efficacy of the translocation program (Koehler and Gilmore, *in prep.*). Searches for *L. raniformis* were undertaken at the farm dam and in both ponds at the constructed wetland (two people per waterbody) using the visual encounter method outlined by Crump and Scott (1994). Searches were conducted on 28–30 November 2010 at the farm dam and on

FIG. 3. The constructed wetland: overview from the north (top) and the culverts (bottom). Note the rock platforms at the end of the dry culvert to assist frogs to exit the water.

17–19 December 2010, 7–9 January 2011, 28–30 January 2011, 15–17 March 2011, and 2 May 2011 at both the farm dam and constructed wetland. On those nights, frogs were captured by hand with the aid of head lamps during a 1-h intensive search which took place between 2100 h and 2300 h Eastern Standard Time. Frog handling followed the "one bag – one frog" approach and equipment was sprayed with a disinfecting solution containing benzalkonium chloride to reduce the risk of spreading infectious pathogens including chytrid fungus (DECC 2008).

Male frogs were identified by the presence of nuptial pads and/or discolored throats (Pyke 2002). Frogs were identified as female if they did not display those secondary sexual characteristics. For some individuals, particularly small specimens without secondary sexual characteristics, the sex of these was classified as "unknown." All 355 captured *L. raniformis* of appropriate size (≥ 50 mm SVL) were implanted with a Trovan Passive Integrated Transponder (PIT) microchip, an approach used successfully to enable the identification of individuals for the congeneric *L. aurea* (Goldingay and Newell 2005). This allowed the movement of translocated frogs to be documented through a mark-recapture program and enabled modeling to estimate survivorship and population size to inform the translocation program (Koehler and Gilmore, *in prep.*).

Marked frogs translocated from the dam were released in both the north and the south pond in roughly equal numbers. Frogs that found their own way to the constructed wetland were released back into the pond where they were captured.

On the basis of the presence of funnel fences and a 100-m-wide fenced corridor linking the northern pond to the farm dam, individual *L. raniformis* were deemed to have moved through the culverts if they were recorded moving from north to south (north pond to south pond or dam to south pond) or south to north (south pond to north pond or south pond to dam).

RESULTS

A total of 158 frogs (64 males, 86 females, and eight frogs whose sex was unknown) captured and marked at the farm dam were translocated into the constructed wetland. Of these, 51 frogs were released into the north pond, 38 into the south pond, and 69 into either the north or south pond (release pond was not recorded; these frogs were excluded from movement calculations unless subsequent captures enabled location to be determined and any future movement documented). An additional 86 frogs (39 males, 43 females, and four unknown) were first found and marked at the constructed wetland (i.e., naturally colonized the wetland or metamorphosed from tadpoles released in November–December as part of the translocation program). Of this latter group, 49 frogs were captured and marked in the north pond and 37 were marked in the south pond. This brought the total number of marked frogs at the wetland to 244 by March 2011.

Movements through the road culvert were documented for 53 individuals (29 males, 23 females, and one unknown, totaling 22% of the total marked population at the constructed wetland). Most of these frogs (43) were recorded as having made one movement while 10 individuals were recorded as having made two movements through the culverts. Collectively, these 53 frogs made a total of 63 movements through the culverts (Table 1). Translocated frogs and frogs that naturally colonized the wetland or metamorphosed from translocated tadpoles contributed almost equally to the number of movements (33 and 30 movements, respectively).

Adult *L. raniformis* were observed on two occasions swimming within and/or floating in the inundated culverts, and two individuals were seen perched on, or in, the outlets of drainage pipes within the culverts at night during the mark-recapture sessions. On another occasion, an adult frog was also observed within the dry passage culvert.

DISCUSSION

We have documented for the first time evidence of the use of an underpass by *L. raniformis*. To our knowledge there are no other published examples of native Australian frogs using box culvert underpasses. To date, only the introduced Cane Toad (*Rhinella marina*) has been recorded using these types of culverts, although native species have been observed at or near culvert entrances (Taylor and Goldingay 2003). We believe our study is the first to document evidence that both male and female *L. raniformis* are capable of using such structures to cross under roads.

A mark-recapture study of *L. raniformis* populations residing either side of the Craigieburn Bypass in northern Melbourne found no evidence of movement of frogs through any of the 10 monitored underpasses built along the road (A. Hamer, pers. comm. 2013). These underpasses included six frog underpasses and four combined culvert and underpass structures, which were

TABLE 1. Movements of marked *Litoria raniformis* through culverts at the constructed wetland between December 2010 and May 2011.*

Sex	Number of frogs making no movement	Number of frogs making one movement	Number of frogs making two movements	Movement north–south	Movement south–north	Total movements
Female	23	23	3	16	13	29
Male	12	29	2	20	13	33
Unknown	0	1	0	1	0	1
Total	35	53	5	37	26	63

* Excludes frogs not recaptured subsequent to first capture or release at the constructed wetland. Frogs considered to have made no movements between ponds may have moved undetected between captures.

TABLE 2. Number of movements made between December 2010 and May 2011 by marked *Litoria raniformis* which colonized the created wetland compared with marked frogs translocated from the dam.

Sex	Translocated from dam		Colonized wetland	
	North – South	South – North	North – South	South – North
Female	8	10	8	3
Male	6	9	14	4
Unknown	0	0	1	0
Total	14	19	23	7

incorporated into the design and construction of the Craigieburn Bypass Project, as a measure to minimize the impacts on the local population of *L. raniformis*. However, in a similar study of a population of *L. raniformis* adjacent to the Pakenham Bypass, Hamer and Organ (2012) recorded a single individual in a wetland on the opposite side of the road to where it was initially marked. They assumed this individual crossed the road by using a bridge underpass at a nearby creek. While it is possible that the frog crossed via the road pavement rather than through an underpass, they considered this was unlikely, since the Bypass has frog-proof fencing installed along its length to prevent *L. raniformis* from accessing the roadway (Hamer and Organ 2012). In this example, the underpass assumed to be used by the frog was an open bridge span over the creek rather than a box culvert type underpass as described here.

Although it is possible that the *L. raniformis* we observed moving between the two ponds did so by exiting the water and traversing overland, we argue that it is far more likely that the majority—if not all—did so by using the box culverts. First, these movements involved a large number of individuals (53), including ten individuals making at least two movements between the ponds. Given the configuration of the frog-proof funnel fences, which both restricted access to the roadway and directed frogs to the culverts, it is unlikely that so many individuals would have crossed the road in this manner. Second, while we did observe one individual (a marked female) on the edge of the roadway on one occasion, we never observed any *L. raniformis* crossing the road or on the road pavement itself. This is despite multiple observers spending many hours over seven months on and near the bridge and roadway at night during the translocation study. Third, several adult *L. raniformis* were observed swimming within and/or floating in the inundated culverts and perched on, or in, the outlets of drainage pipes within the culverts at night, demonstrating that the species did not avoid the interior of the culverts. Last, being a highly aquatic species and a powerful swimmer, we believe *L. raniformis* is well adapted to, and capable of, traversing the inundated culverts of the underpass and we can see no obvious reason why individuals would not readily swim through them.

We believe that the inundation of three of the four culverts in our underpass example, which hydrologically linked constructed aquatic habitat on one side of the road to the other, improved its suitability for use by *L. raniformis*. While it is possible that individuals did use the single dry culvert, only one frog was observed in the dry culvert and on only one occasion. This is perhaps not surprising given the species' largely aquatic habits. A dry culvert was incorporated into the design at Epping North on the basis of recommendations by Robertson (2002). While further study is required, our results suggest that incorporating a dry area into the culvert design of relatively short road crossings may not be necessary for the highly aquatic *L. raniformis*. The inclusion of a dry area within a culvert remains prudent in situations where a culvert is necessarily long and there is a risk of adult frogs drowning or in instances where there are other species that may use the culvert. In these cases, dry refugia can be incorporated within inundated culverts (e.g., through the strategic placement of "islands") as an alternative to a completely dry culvert.

Caution should be exercised before extrapolating the results of this study to the effectiveness of other culverts designed for use by *L. raniformis* (e.g., culverts that are completely dry, culverts with smaller dimensions, culverts located away from drainage lines). The use of underpasses that differ from that described here is yet to be proven and further research is required to determine the effectiveness of different designs. Similarly, the suitability of the culvert design described here for use by other anurans is unknown. This is particularly true for species whose ecology is different from *L. raniformis* (i.e., species whose adult life history stage is largely terrestrial).

Although we have only examined one site, our observations indicate that culverts designed to facilitate the movement of *L. raniformis* may be most effective when they are permanently inundated and are hydrologically linked to aquatic habitat on either side of the culvert. If comparative studies of different culvert designs shows this to be the case, constructed waterbodies on either side of the road could be designed to also provide breeding habitat for *L. raniformis*, as this is likely to increase the number of frogs within the vicinity of the culvert entrances and hence enhance connectivity between populations either side of the road. Inundated culverts may also facilitate the movement of *L. raniformis* tadpoles from one side of a roadway to another, which could further enhance population connectivity.

It is important to emphasize that for *L. raniformis*, the primary reason for constructing wetlands at culvert entrances should be to enhance connectivity of habitats on either side of a roadway. Such wetlands should not be relied upon as compensation for habitat removed elsewhere (e.g., for urban development). Additional wetland habitat should either be retained (preferable) or created (where retention is not possible) away from the vicinity of roadways to account for the potentially negative influences roads may have on this species, such as disturbance, noise, road mortality, and pollution.

Acknowledgments.—We thank Biosis Pty Ltd for funding the study and Places Victoria for permission to undertake the work. We thank Chris Bloink, Tony Byrne, Aaron Harvey, James Hill, Felicity Humann, Clare McCutcheon, Wanda Robinson, Thea Shell, Ian Smales, Katrina Sofo, Katie Stevenson, and Mark Venosta of Biosis, David Newell of Southern Cross University, Geoff Heard and Claire Keely of Melbourne University, Luke Geddes and Marion Shadbolt for volunteering their time to assist with the field surveys. Ian Smales of Biosis provided advice on data interpretation and Sally Mitchell and James Shepherd of Biosis assisted with the preparation of figures. David Newell also provided advice and training in PIT tagging. Ian Smales and Matt Dell of Biosis and Andrew Hamer and Rodney van der Ree of the Australian Research Centre for Urban Ecology kindly reviewed early drafts of the manuscript.

The constructed wetland was collaboratively designed by a team comprised of Biosis, Spiire Australia and MDG Landscape Architects, on behalf of Places Victoria and in consultation with the Department of Sustainability and Environment, Whittlesea City Council and Melbourne Water.

This study of *L. raniformis* was undertaken in accordance with Research Permit 1004816 (live capture and release) and Research Permit 1005625 (PIT tagging) issued by the Department of Sustainability and Environment under the *Wildlife Act* 1975 and approval 03.09 from the Wildlife and Small Institutions Animal Ethics Committee of the Bureau of Animal Welfare, Department of Primary Industries. Salvage and translocation of *L. raniformis* was undertaken in accordance with Management Authorisation no: 10005067 issued under the *Wildlife Act* 1975 by the Department of Environment and Primary Industries.

Herpetological Research at Primarily Undergraduate Institutions

A tradition exists, extending from colonial days into the 20th and 21st centuries, of herpetologists who have done remarkable work, but who have no formal training in herpetology. Individuals such as Raymond Ditmars, Lawrence Klauber, Joseph Slevin, Roger Conant, Hubert St. Girons, and Ernest Liner come quickly to mind, but many other people could be aligned with this group. These individuals, of course, were never the academic mentors of Ph.D. students in herpetology, but they greatly influenced research in herpetology. Likewise, many other herpetologists in the past and present have held academic positions at institutions where the focus is not on research, publishing, getting grants, and training Ph.D. students. In this perspective, we demonstrate that herpetologists holding positions at strictly undergraduate institutions or those in which the terminal degree is a Master's can nevertheless have productive careers in research. Also, herpetologists at primarily undergraduate universities can impact the future of herpetological research by inspiring undergraduate students to take up herpetology early in their careers.

Collectively, the contributors to this essay have nearly 100 years of experience working for various institutions of higher education. One of us (RP) has spent his entire career at a liberal arts college, another's (SJM) career has been entirely at regional comprehensive universities (RCU) where the M.S. degree is the highest awarded, and the lead author (DMS) has taught at both types of schools. In thinking about what has contributed to our relative levels of success (and enjoyment) in each of our positions, we decided to focus on three elements of maintaining a research program at schools that place greater emphasis on high-quality teaching: 1) Sustaining a long-standing research program; 2) attracting high-quality students (with emphasis on those seeking graduate degrees) to participate in the lab's research productivity; and, 3) collaborations and publishing with student authors. Instead of generating a step-by-step "how-to" guide for our colleagues at primarily undergraduate institutions, we use our experiences to illustrate means of achieving success.

Funding Undergraduate Research – Sever

My lab has concentrated for 40 years on using histological and ultrastructural techniques to study the comparative anatomy and phylogeny of primary and secondary sex characters of amphibians and reptiles. I spent the first 30 years of my career at Saint Mary's College, Notre Dame, Indiana, which is a small comprehensive college (1500 total students, all women) that grants only Bachelor's degrees, and since 2004 I have been at Southeastern Louisiana University (SLU), at which the Masters is the terminal degree. My teaching load has always been 9–12 contact hours per semester, and in addition, I served as department head at both institutions for a total of 16 years. Neither institution has great demands on faculty to do research. Indeed, at both schools, an assistant professor after six probation years can obtain tenure with only one or two publications during that period. I have never been pushed by administrators to get grants or publish papers. Whenever either activity occurred, however, administrators were pleased because they recognized that research, especially involving students, should be an integral part of the undergraduate curriculum.

I will emphasize three ideas in this section: 1) Create a research program that can work at an undergraduate institution. This research program should have the potential to grow and attract funding and students. 2) Submit grants at all levels, from $1,000 travel grants to $400,000 NSF grants. Many granting agencies like to see stipends for undergraduates listed on proposals, and NSF even has a special niche (RUI) for proposals from undergraduate institutions. 3) Get undergraduate students involved in your research. Powell will expand on this topic later in this article, but I will show how success in funding of grants leads to opportunities for undergraduates. The wide-eyed enthusiasm of undergraduates can be contagious around a lab and can make even routine fieldwork more enjoyable. These three ideas are not independent of one another and are interwoven in the narrative below.

I became a "histo-herpetologist" during my doctoral work at Tulane University, where my research involved the light and electron microscopy of secondary sexual characters of salamanders. When I arrived at Saint Mary's College in 1974, the fundamental instruments needed to do histological research were present and all I needed was expendable supplies. As such, my "start-up" cost the school less than $1,000. I needed to obtain some grants to provide money for travel to collect specimens and to replenish expendable items. I also saw the need to explore ways of obtaining an electron microscope for Saint Mary's. I realized that it might help to be unique—I also needed to make my work compelling; why should NSF support this?

My first grant at Saint Mary's came from the Highlands Biological Station, where I had worked during my doctorate, and allowed me to obtain more samples of salamander tissues. Then I discovered that the Indiana Academy of Science was quite generous in awarding modest grants to work on the local fauna, and I started what turned out to be long-term studies on a population of *Ambystoma tigrinum* near campus. Saint Mary's, like many colleges, also had its own internally funded faculty research grant program, and I applied for these frequently. Funds were also obtained from the state Department of Natural Resources and the American

Philosophical Society. So I actually had enough money to sustain my modest histology lab. The first papers co-authored with undergraduates on *A. tigrinum* (DeNeff and Sever 1977; Couture and Sever 1978) were published in the *Proceedings of the Indiana Academy of Science*. The student authors not only had a publication but also the experience of presenting their work before the Academy.

During the mid-1980s, the College started a renovation project on the Science Hall, and I convinced them that they needed to include an electron microscopy suite. The commitment of the College probably helped the success of my 1987 proposal to NSF, "Electron Microscopy in the Undergraduate Biology Curriculum," which resulted in the addition of a transmission electron microscope (with a scanning electron microscope attachment) and the necessary peripheral pieces of equipment. I immediately began teaching an electron microscopy course in which the undergraduates were trained to conduct ultrastructural research (on amphibians and reptiles, of course). The same year that I received the grant for the electron microscope, I received my first NSF research grant, "Comparative Anatomy and Phylogeny of Cloacal Glands in Salamanders." So 1987 was a pretty good year.

Undergraduate students continued on various projects, including research on *Ambystoma tigrinum* from our study pond (Sever et al. 1987; Platt et al. 1993), but a number of students began working for me on my cloacal gland grant, including some who served as full-time research assistants during the summer. When that grant ended, I received NSF funding in 1991 for a new project, "Comparative Cytology of Sperm Storage Organs in Female Salamanders (Amphibia: Caudata)." This research involved ultrastructural studies on the spermathecae in all families of salamanders that possess the glands. The presence of an electron microscope, made possible by NSF funds, probably was a factor in the success of the proposal. The research included considerable undergraduate student involvement, starting with papers by Sever and Kloepfer (1993) and Sever and Brunette (1993) in the *Journal of Morphology*. During this period, I also began collaborations with graduate students working at the Savannah River Ecological Laboratory (SREL), including John Krenz, Travis Ryan, and William Hopkins. The Department of Energy had a simple process that provided ample travel grants (that included airfare, rental car, and motel) for work at SREL.

Toward the end of my time at Saint Mary's, I became interested in squamate reproductive anatomy. Travis Ryan sent me samples of *Seminatrix pygaea* collected throughout 1998. Tissues harvested from these samples provided the data for seven papers between 1999 and 2010, making *S. pygaea* the most intensely studied reptile in terms of urogenital organ ultrastructure. Again, undergraduate students were critical to accomplishing this research—four from my electron microscopy class were co-authors on one paper (Sever et al. 2000).

I left Saint Mary's to become Department Head of Biological Sciences at SLU in 2004. I will not dwell on my experience with Master's students at SLU, as Mullin will discuss graduate students in the next section. I am pleased, however, that the five MS students I mentored between 2005 and 2011 have gone on to Ph.D. programs, and three have completed their doctorates. Also, I have continued to receive funding from internal sources; such grants are available from SLU and the Louisiana Board of Regents. From NSF, I received funding for a proposal, "The Evolution of Sperm Ducts and Accessory Sex Glands in Squamate Reptiles: An Empirical Study of Cellular Complexity." This support once again allowed me to hire undergraduate students (as well as Master's students) to assist with my research and become co-authors on papers.

In summary, I carved out a niche in comparative anatomy of reproductive structures of amphibians and reptiles that has proved to be very productive over the years. I am pleased that I have mentored students like Dustin Siegel and Justin Rheubert who will carry on this work. My message to graduate students looking for academic positions and to young assistant professors who find themselves at largely undergraduate institutions is simple: If you love your research, you will find time and funding to do it, and you will find undergraduate students who will be eager to participate. You will be as productive as you want to be.

Attracting Graduate Students – Mullin

For the foreseeable future, certain elements of the screening process for graduate students will be constants—things like GPAs, GRE scores, personal essays, and letters of recommendation. Through experience, we assume that successful faculty members have arrived at their own mechanisms by which they comfortably prioritize these metrics in a manner that helps them gauge each student's potential (so I will not write about it here). Having already read Sever's recommendations for supporting a research program through sustained grantsmanship, I have also included little mention about how the successfully recruited student should be funded. Instead, this portion of our article identifies aspects of recruiting and qualitatively evaluating prospective graduate students, with emphasis on elements worth considering for those researchers at RCUs. I focus on four particular attributes: Independence and motivation, good communication skills, prior experience in a related setting, and good camaraderie. In many respects, these attributes are also useful when involving undergraduates in the lab group's research endeavors.

A recurring sentiment of the recent Master's graduates from my lab is that attending an RCU has a distinct advantage over an R-1 school—after the major professor, the Master's students are typically the "top dogs" among lab members. From discussions with their peers in larger labs (that have hierarchies that include post-doctoral researchers and doctoral students), my graduate students find themselves in a fortunate position for several reasons (items worth mentioning as you get to know prospective students): 1) Consistent access to their major professor, without needing to yield time to more senior members of the lab group. 2) First priority in selecting research assistants. Like most researchers conducting field projects, few efforts in my lab are completed without a small army of undergraduate researchers. In the absence of post-docs or Ph.D. students who might pull rank to work with the "pick of the litter," Master's students at RCUs can rarely complain about not having enough assistance available. 3) Greater opportunities for funding research. This might seem counter-intuitive, but Master's students in my lab typically appreciate trying their own hand at writing grant proposals instead of structuring their thesis research to fit within the scope of an existing grant authored by their professor. Whereas RCUs typically do not have as much funding from major agencies like NSF and NIH (see, however, Sever's comments above), opportunities for Master's students to acquire their own funding (especially from intramural sources or extramural agencies that do not allow the school to siphon off overhead costs) can be more numerous than at R-1 schools. 4) More opportunities for intellectual independence and growth. This is a corollary of the

previous point in that, by completing a project that is not tied to an existing research grant (often one with a much larger scope), Master's students at an RCU typically have a little more freedom to pursue those interests that crank their intellectual engines the most.

Implicit in Sever's contribution to this essay is a fortunate paradox—although much of the general public cares little for the organisms that we study (especially snakes; Seigel and Mullin 2009), our focal animals are endowed with a charisma that attracts a steady stream of interest from undergraduates in our academic units. Faculty working at RCUs can exploit this interest when needing help on either their research projects or those of their graduate students. Convincing undergraduates that studies involving amphibians or reptiles are both fun and fulfilling is an easier task than assuring that your lab benefits from steady and reliable help from those students. Two strategies have helped maintain my lab's productivity: 1) I identify students early by recruiting them from lower-division courses; and, 2) I assess the student's commitment level and aptitude by involving them in lab activities that do not necessarily involve interactions with our focal animals. For instance, weekly lab meetings provide the opportunity to discuss a recent publication or critically review a grant proposal. Initial levels of enthusiasm from recruited undergraduates might wane in the face of such activities, and I often use this as a surrogate measure for their level of dedication to an actual project.

Students maintaining or increasing their interest levels in all lab activities gain additional experience, and assure some continuity in the lab's operations—whether a long-term project or the husbandry of a research colony of animals, students who are new to the lab group receive effective training from both experienced undergraduate and graduate students. Herein lies another advantage, but this time for the student: engaged in this manner, research-minded undergraduates gain a variety of experiences, thereby enhancing their chances at succeeding beyond their bachelor's degrees. I not only use this as a selling point when recruiting undergraduates, but I look for evidence of breadth and depth of experience among prospective graduate students, even if they were not able to pursue their own project independently.

One of the best, albeit indirect, pieces of advice from my undergraduate advisor was to experience different settings for my graduate degrees. Compared to continuing an association with what was already familiar to me, exposure to new teaching and mentoring paradigms and to the herpetofauna in different ecosystems better prepared me for a successful academic career. Completing each of my degrees at different universities also helped me develop a sense of independence and self-motivation. I now offer this advice to my own students: Although undergraduate assistants in my lab might have stellar GPAs and an acumen for research that would rival most doctoral students (such that I would enjoy continuing as their mentor), I nevertheless encourage them to move on to another school for their Master's degrees. I also look for the traits that would typically be cultivated by such a move—independence and motivation—in prospective graduate students. When considering students from other schools, I find that those who want to complete a Ph.D. (whether immediately after their tenure in my lab or eventually) are the same individuals who are most successful as Master's students. They recognize that working in my lab group will be a training ground for the greater demands expected at a doctoral program. This recognition also manifests itself in the motivation needed to see a research project through to its logical conclusion (i.e., a peer-reviewed publication).

To end up with the best possible graduate students in a lab, successful professors must first ensure that their efforts are on the radar of the community at large. In addition to a steady publication record, I have found that one of the best ways to make this happen is to attend the joint meetings of the three North American herpetological societies (JMIH). Not only do I renew friendships with colleagues who "grew up" with me as graduate students at previous iterations of this conference, but I typically learn about promising undergraduates from other labs who have expressed an interest in getting experience in other programs. Meeting prospective students in this setting might include opportunities to get a sense of how the students discuss their science (say, if they are presenting undergraduate projects). Given that graduate students are regularly the public face of your lab, you will want to recruit students who can speak clearly and confidently about their own work. Interacting with prospective students at meetings like the JMIH also gives you more information about their potential fit into the current composition of the lab than could be obtained from an email inquiry with an attached CV.

At some point during the bi-directional screening process, I encourage prospective graduate students to visit my lab. A few colleagues at other universities (ranging from R-1s to RCUs) insist on this sort of interview visit as part of the application process, perhaps as a means of assessing the degree of student commitment. I do not feel comfortable making this demand because, typical of an RCU, the school has no funds to help offset the costs of such trips. I do what I can to lessen the outlay in the form of providing housing (usually imposing on a current graduate student) and a few meals. The prospective student not only comes to understand the potential academic aspects of joining your lab, but also learns more about the domestic and social life of a typical graduate student. To help the prospective student realize the most from investing the time and effort into the trip, I arrange brief interviews with other faculty having some overlap in research interests. Thus, the student can appreciate the diversity of expertise that would be available during his or her degree program; meanwhile, I learn of any "red flags" that are raised in the minds of my colleagues that might not have been apparent during my own interactions with the student. As helpful as such a visit can be in ascertaining the chemistry between the major professor and student, it is equally important for me to know that the prospective student will get along well with current lab members. As I have already invested resources into the existing makeup of the lab (and have established good working relationships with those students), I would be doing the group a disservice by accepting a new student whose ideology (e.g., Gregory and Ellis 2009) or personality clashed with those of other lab members.

Collaborations and Publishing with Students – Powell[1]

At small schools that lack graduate programs in the sciences, herpetologists are considered rather generic biologists who are asked to teach courses ranging from introductory biology to upper-level courses such as anatomy, embryology, ecology, and evolution. Once exposed to the charms of amphibians and reptiles, however, reverting to generic biology can be a bitter pill. Furthermore, because teaching is the primary responsibility of

[1] Portions of my contribution are adapted from an essay published in 1998 in *The Newsletter of the Herpetologists' League* (5[1]:5–6).

faculty at such institutions, heavy course loads, plus ancillary responsibilities such as advising and committee work, leave little time for research. That said, "doing" herpetology at a small school is not impossible, but constraints like time, space, and funding are real and must be acknowledged. The impacts of these constraints are lessened by the fact that many small institutions are tuition-driven—meaning that any activity that attracts, involves, and retains students will be viewed positively by administrators. The obvious solution, of course, is to engage students in herpetology. One of the most powerful attractants is participation in field trips. These need not be to exotic climes (although that is nice); local and regional trips are inexpensive, take little time, and can open the eyes of students to realities of nature that most have never experienced.

As a new faculty member at Avila University, I sought to provide my students with some of the same experiences responsible for leading me to a career in academia. I developed what I called a "field biology" course, for which students could earn credit for having a great time and gaining experience. Our first trip was to the Big Bend, and it went so well, I immediately began planning trips to more esoteric destinations even farther south. Over the next few years, I taught field biology classes around trips to Baja California, the Yucatan Peninsula, and various other destinations in México. As acquiring permits in México became increasingly difficult, I began looking for alternative destinations. At the time, I knew no one working in the West Indies, but Bob Henderson, with whom I had corresponded regarding our work in the Yucatan, had been focusing his work on Hispaniolan treesnakes (*Uromacer*). I gave him a call to ask if he thought the Dominican Republic (DR) would be a good place to take students. He not only said it was, he sent me a thick packet of information regarding whom we should see about permits, where to stay, and from whom to rent vehicles. My wife and I took a short "vacation" that January, and I took my first field biology class to the DR that spring.

The early trips were all about finding critters, but I soon began looking for projects that could be implemented during short periods—and these gradually became more sophisticated and elaborate as I became more familiar with the herpetofauna. One day, the advancement office at Avila forwarded an NSF document announcing criteria for a new program titled "Research Experiences for Undergraduates" (REU). I immediately recognized the potential to do an even better job of what we had been doing all along. I sat down with John Parmerlee, who had been a student during my early days but had since earned a graduate degree, returned to the area, and had accompanied me on many of the field biology trips—and we wrote a proposal in a day and a half.

As might be expected, that first effort was pretty marginal. We learned from reviewers' comments, however, and took considerably more time the following year, which resulted in many positive comments—but no grant. So, I contacted the program director and asked for an explanation. I learned that no one on the review panel knew me or had ever heard of Avila. That, combined with the "unusual" nature of our proposal—we proposed keeping the student cohort together in the DR, have them engage in individual or collaborative projects, and publish their results—led to the lack of funding. I think my conversations with the program director led to her giving us a chance.

Focusing on natural history and establishing publication as a goal from the very beginning, we selected our first cohort in 1991. Every participant became an author, we collectively contributed to a growing knowledge base concerning the West Indian herpetofauna, and clearly demonstrated to NSF that we could achieve what we had proposed. We have now conducted 11 iterations involving 101 students from 68 different colleges and universities, all of whom have been at least coauthors of at least one of over 150 publications in peer-reviewed journals[2]—and the great majority have matriculated to graduate programs. Furthermore, several former students have served as faculty in subsequent programs, either while still in graduate school or after having become faculty members at institutions of various types.

Although I still have students developing and implementing projects locally, often relying on museum specimens borrowed for that very purpose, I have adapted much of my research to the REU programs. This allows me to remain actively engaged while simultaneously providing my students with a leg-up toward research careers of their own. I would further suggest that our type of program is not only beneficial to the participating students, but unique to an undergraduate institution. Because I do not have to maintain a lab that meets the needs of graduate students or postdoctoral fellows, I can devote entire summers to research involving undergraduates. Furthermore, by focusing on natural history in its various guises, I can provide students with an entire research experience, from developing and implementing hypothesis-driven projects to publishing the results of their work.

Publication is an important and worthwhile goal for undergraduate research. It represents the culmination of the research process, provides opportunities for teaching (and learning) relevant and essential skills, and it generates a product that not only enhances a student's CV, but validates the research experience and makes a contribution to science. Not all research is appropriate for publishing with undergraduates and hurdles can be substantive. Sometimes the undergraduate lacks the necessary competence, some research protocols are too complex to provide undergraduates with more than a small portion of the process, and the time involved can be daunting—but these obstacles are not insurmountable, especially if publication is established as a goal from the very beginning.

Undergraduate research is more likely to be publishable if it addresses subjects about which little is known, reducing the burden of breaking new ground. Good research does not have to be "cutting-edge" science. My collaborators and I address this in our field-based work by going places where little research has been done, where many of the basic questions remain unanswered (e.g., diets, distributions in variously altered habitats, some aspects of behavior and performance), and abundant data can be generated in relatively short periods of time. Collaborative endeavors further enhance data collection (although they inevitably lead to discussions regarding senior authorship) and conserve time. Time constraints also dictate investigative protocols with shallow learning curves. Those, however, allow us to supplement a core of more advanced and experienced students with bright freshmen and sophomores or students from institutions that lack the means or facilities for research.

Mentors must be willing to invest huge amounts of time and must resist the temptation to simply take over and do the job themselves (although a more heavy-handed approach may be necessary when tackling a first experience with statistical techniques). They also must avoid imposing unrealistic expectations. Like learning any other skill, practice is necessary and

[2] Additional information and a list of publications is available at www.avila.edu/bobpowell/7powreu.htm.

opportunities to practice must be provided. Mentors must work with students as they learn the necessary investigative skills, but be willing to step back when students are capable of taking charge of a project. Finally, even the best students must learn to write for publication. During this process, mentors must be patient—reviewing draft after draft, criticizing without discouraging, encouraging without demeaning, and not streamlining the process to the extent that they think it is easier than it actually is. This often extends well beyond the 10-week summer program, explaining why we schedule our trips in alternate years.

From the early days of weekend field trips and publications dealing primarily with range extensions or county records to increasingly sophisticated studies demonstrating, for example, relationships of laboratory-generated data on performance to real-world situations, the scope of my research has changed—but the emphasis on student engagement has remained the same. So, being a herpetologist at a small undergraduate institution can be challenging, but it can be done and done well. Hard work and accepting and overcoming the inherent obstacles are essential.

Conclusion

Woven into our essay is the important theme of research experience—whether yours or that of students in your lab. We enjoy conducting it, our students enjoy helping us, and, even when the recognition rarely comes in the form of release time or infrastructure improvement, our administrators love to tout the fostering of critical thinking skills in our students when we involve them in research. In this sense, we get some of the same benefits from being research-active without the stress of the "publish-or-perish" environment that typifies most R-1 programs. The lower pressure at a college or RCU also increases the likelihood that a researcher can be successful in the particular niche of conducting long-term studies (e.g., decadal in scale). Prospective students not only express interest in conservation-related research with increasing frequency, but they are easily convinced that long-term studies can better inform conservation strategies because such a perspective accounts for more environmental variability. Because teaching excellence is favored over research output at our institutions, we can publish more comprehensive views of particular systems based on data compiled over multiple years.

Engagement in research provides you with the mechanisms to stay abreast of advances in your field (e.g., through presentations at meetings, current literature, publishing with students, etc.), informs your teaching, and, in theory, keeps you intellectually sharp (responding either to questions or feedback from manuscript reviewers). For students in your lab group, training in a research environment builds critical thinking skills, invests them in the process of scientific discovery (Moslemi et al. 2009), and will help prepare them for many of the next steps in their careers (Fleet et al. 2006). We expect our colleagues have also realized that, by involving students in research early in their development as biologists, the students quickly recognize that careers in herpetology are equally valid to those that focus on other taxonomic groups—our field would perish if new cohorts of students were not impressed by the processes of answering questions about amphibians and reptiles and generating the results that lead to new questions. Admittedly, we have not covered every single aspect that will allow you to remain research-active at a non-R1 institution. Rather, our hope is that the coming cohorts of newly-minted Ph.D.s and post-doctoral fellows will be encouraged by the opportunities at primarily undergraduate institutions, and take comfort in the fact that, in these settings, they can continue to contribute in meaningful ways to our understanding of amphibian and reptilian biology.

Acknowledgments.—We thank our own advisors for sharing a few insights on mentoring student researchers. Feedback from S. Boback, R. Brodman, M. Dorcas, and N. Ford improved previous drafts of this paper. Most of all, we thank the students who have worked in our lab groups (both undergraduate and graduate) for their enthusiasm and perseverance in many research endeavors with such fascinating animals.

Utilizing Hydrophobic Coatings for Maximizing Venom Extraction Yields

Reptile venoms and their individual molecular components have evolved to target and control crucial biological functions (St. Pierre et al. 2007; Chaisakul et al. 2014). Understanding how venom manipulates life systems has clinical implications (Earl 2012; Koh et al. 2012; Harvey and Stocklin 2012; McClearya et al. 2013; Utkin 2013; Venkatesh et al. 2013; Vink et al. 2013) as well as ecological and evolutionary implications (Barlow et al. 2009; Richards et al. 2012; Benard-Valle et al. 2014). Mass spectrometry, gene sequencing, and other precise techniques for furthering toxicological research are now commonplace in many biochemistry labs, and novel discoveries are increasingly dependent on the availability of crude venom for analysis (Calvete et al. 2009). The production of antivenoms is also dependent on accessibility of crude venom (Gutiérrez et al. 2011; Gutiérrez 2012). Scientific advancements in these areas will depend heavily on interdisciplinary collaboration to maximize efficiency in the venom research process. The first, and most dangerous step in the process is collecting venom from the individual organisms.

Venom extraction facilities rely heavily on the efficiency of extraction equipment to maximize venom yield per extraction and reduce the number of extractions needed. This in turn reduces risks for the extractor and limits stress on the animal. The general procedure for extracting venom from species exhibiting high pressure delivery systems (e.g., elapids and viperids) has remained unchanged for decades (Willemse et al. 1979; Savanur et al. 2014). The process involves eliciting venom delivery into a glass or plastic collection container through a wax membrane. Since venom is a viscous substance, some of it inherently adheres to the extraction equipment and is lost (Fig. 1). To address this issue the following study was conducted in order to determine if there is a way to reduce venom loss during the extraction process. To minimize residue left on glass during extractions two coatings were tested and their efficacy determined for reducing the adherence of a surrogate venom mixture to glass funnels.

Materials and methods.—Two KIMAX® glass funnels (75 mm diameter with 58°-angle bowls) were thoroughly cleaned (using dish soap, dilute bleach, and a hot water rinse) and sent to Nanotech Coatings© (Glenwood Springs, Colorado 81601, USA; www.nanotechcoatings.com) to be coated with commercially available water-repellant coatings. The coatings were applied by Nanotech professionals using a compressor sprayer to produce even coats on all surfaces of the funnels (application details are available on the Nanotech website). One funnel was coated with the product "NanoTech Coatings Quick Seal & Enhance" (SKU: NANO10061) and the other with the product "NanoTech Coatings Marine Coating" (Marine Coating SKU: NANO10001, Catalyst SKU: NANO10017). These were both chosen for their commercial value of repelling aqueous substances while remaining active after cleaning and moderate abrasion.

Actual venom was not used for testing in order to limit venom waste. To simulate venom, a proteinaceous solution was made consisting of one gram of commercially available unflavored gelatin (Kroger© brand) per 10 ml of warm water (35°C) which was left for 30 minutes to cool to room temperature (25°C). The resulting mixture was a syrupy solution resembling the viscosity of venom, and more was made as needed between tests. A 1-ml syringe and 27-gauge needle (Nipro© brand) served as a substitute venom delivery apparatus (Fig. 2). Expulsion rate was kept at 10 seconds per full syringe and 30 seconds was spent refilling the syringe in between each expulsion. This technique allowed the surrogate venom to dry somewhat just as real venom would while the extractor moves from one specimen to the next during a live extraction session.

One uncoated control funnel and the two coated funnels were compared for yield efficiency using the surrogate venom and substitute delivery system. The testing setup mirrored a typical live extraction setup and included a collection vial and extraction stand (Fig. 2). To quantify the differences, each funnel was subjected to ten mock extractions, five representing a 10-ml extraction and five representing a 3-ml extraction. Ten syringe expulsions were utilized through the 1-ml syringe for each of

e-mail: michael.hogan.p@gmail.com

the 10-ml tests and three expulsions for each of the 3-ml tests. Funnels and collection vials were independently weighed before and immediately after each test using a digital scale (Myweigh© DuraScale D2 300, 0.01 g accuracy). The glassware was thoroughly rinsed with hot water (55°C) and dried in between subsequent tests such that initial weights were consistent (± 0.01 g). A ten-minute grace period between tests allowed the glass to return to room temperature.

The total weight of surrogate venom from each test was determined by subtracting the initial weights of the funnel and vial from the post-mock-extraction weights. The percent lost as residue on the funnel was established using the total surrogate venom and funnel residue weights from each test. Mock extraction tests were completed five times for each treatment (N = 5), where the variables included the three different funnels (control, "Quick Seal & Enhance," "Marine Coating") and two extraction sizes (10 ml, 3 ml). A one-way ANOVA and Tukey post-hoc test was performed on these percent values to determine the statistical effectiveness of the coatings for large and small extractions.

Results.—The one-way ANOVA and Tukey post-hoc test revealed the "quick seal enhance" provided a significant decrease of mock venom residue on the glass funnels ($P < 0.01$) for both the large (F value = 21.68, degrees of freedom = 2) and small (F value = 11.29, degrees of freedom = 2) extractions when compared with the control. The "marine coating" showed a significant decrease in residue only for the large extraction ($P < 0.01$) when compared to the control. Summaries of the performances of the funnels can be seen in Table 1.

Discussion.—The smaller 3-ml tests resulted in larger percentages of total surrogate venom left on the funnel as residue when compared to the percentages from the larger 10-ml tests. This difference was almost 2% between the controls for 10 ml and 3 ml testing sizes (4.83% and 6.54% as residue, respectively). This is important since the venom from species with smaller yields (such as *Micrurus* species) is coincidentally more difficult to study, which makes every drop valuable to both researchers and extraction facilities (J. Harrison and K. Wiley, pers. comm.). From this observation it was concluded that extracting more venom at a given time results in a higher percentage of venom collected and lower percentage lost as residue. The funnel coated with the "quick seal enhance" resulted in the least amount of surrogate venom residue in both the 10 ml and 3 ml tests (1.42% and 3.54% as residue, respectively) and was therefore deemed the superior coating tested. This coating lowered the amount of residue by 3% when compared to the controls for both the 10-ml and 3-ml tests. This translates to a net gain of almost a full gram of dried venom for every 300-ml of liquid venom extracted when utilizing this coating. Under normal circumstances the KRZ collects at least this amount of venom weekly and the director has reported collecting double this amount in one day (J. Harrison, pers. comm.).

The coatings are expected to be inert when exposed to actual venom. However, venom samples should be tested for contamination initially before wide-scale implementation of this technique since some trademark ingredients in the coatings are undisclosed. The coatings may modify certain venom molecular activity and/or structure. In the event that direct fang contact jeopardizes the longevity of the coating from prolonged abrasion, certain preventative modifications can be made such as limiting the coating to just below the fang contact point.

This preliminary study was completed in order to portray the potential of utilizing glass coatings for extraction efficiency. There are countless other hydrophobic coating products available for testing which may outperform the two selected for this study. There may also be high potential in implementing super-hydrophobic technology in venom extractions. Unfortunately a stable and reliable super-hydrophobic product has not yet been made readily available for testing of this sort. Understanding the physical boundaries involved with super-hydrophobic and liquid-tension technology may also have relevant implications (Kleingartner et al. 2013). Behavioral research such as strike behavior and venom expenditure may open doors towards safer and more efficient extractions (Young and Zahn 2001; Deufela and Cundall 2006; Hayes

FIG. 2. Mock extraction set up, courtesy of KRZ. Visible residue on control funnel.

TABLE 1. Summary of the surrogate venom residue values from the 10 ml and 3 ml mock venom extractions. Shown are means of percent values from the five tests completed for each treatment, representing the percent of total mock-venom left on each funnel ± standard deviation (N = 5 for each treatment, 1 = 100%).

Mock extraction amount and funnel treatment		Residue (% of whole), SD
10 ml	Control, no coating	.0483 ± .01523
10 ml	"Bonding Coat" and "Quick Seal & Enhance"	.0142 ± .00427
10 ml	"Bonding Coat" and "Marine Coating"	.0152 ± .00295
3 ml	Control, no coating	.0654 ± .01487
3 ml	"Bonding Coat" and "Quick Seal & Enhance"	.0354 ± .00508
3 ml	"Bonding Coat" and "Marine Coating"	.0489 ± .00723

2008; Hayes et al. 2008; Herbert and Hayes 2008). Modifying the equipment based on physiology may also prove advantageous in studying various species for which extraction may be particularly difficult (e.g. *Atractaspis*).

Acknowledgments.—This preliminary study was completed in collaboration with KRZ, under the direction of Jim Harrison and Kristen Wiley. Usage of extraction and laboratory equipment were generously provided for this study by KRZ. The specific coatings were chosen in collaboration with Megann Grett-Pratt, who represented NanoTech Coatings© for this study. She understood the purpose of the tests and recommended which coatings to use. Each coating is listed as environmentally friendly and void of volatile organic compounds. The safety specifications and more information for all the coatings used can be found on the Nanotech website: http://www.nanotechcoatings.com/.

Attaching Radio Transmitters Does Not Affect Mass, Growth, or Dispersal of Translocated Juvenile Tuatara (*Sphenodon punctatus*)

The IUCN guidelines for conservation translocation (IUCN/SSC 2013) emphasize the importance of post-release monitoring. Such monitoring provides a feedback mechanism to update and enhance current protocols for translocations (Armstrong and Seddon 2008). Monitoring using radio telemetry can be a valuable method for accruing post-release information, including estimates of survival, habitat use and dispersal distance (Le Gouar et al. 2012). Telemetry is an effective technique for studying lepidosaurs (tuatara, lizards, and snakes), many of which are cryptic and/or have secretive behaviors that make them otherwise difficult to detect. An important assumption of telemetry-derived data is that tagged individuals are not adversely affected by the attached devices (White and Garrott 1990), yet many studies do not specifically address the effects of radio-tagging on animals (Millspaugh and Marzluff 2001). The Tuatara (*Sphenodon punctatus*), an endemic reptile of New Zealand, has been reintroduced to Orokonui Ecosanctuary (hereafter Orokonui; Te Korowai o Mihiwaka; 45.766°S, 170.6°E) in the southeastern South Island of the country. In total 87 animals, including 57 juveniles, have been translocated. Tuatara are diurno-nocturnal, burrowing reptiles with low detection probabilities (Cassey and Ussher 1999), particularly for juveniles (Dawbin 1982). We used radio telemetry to monitor dispersal distance and habitat use of juveniles during the establishment phase (IUCN/SSC 2013). Telemetry has been employed for monitoring adult Tuatara, but has rarely been used on juveniles (Table 1). A pilot study was first performed to try several attachment methods. We then compared the performance of tagged versus untagged juveniles that were free-released into the ecosanctuary. Specifically, we evaluated whether body mass, growth rates, and dispersal behaviors differed between tagged and untagged juveniles over five months following release.

Pilot study methods.—In the pilot study we used dummy transmitters (ovoid beads, clay molds, or non-functional transmitters) that were approximately the same size (23 mm × 12 mm × 7 mm, LWH) and mass (3.9 g) as the functional transmitters (PD-2T, Holohil Systems, Carp, Ontario, Canada, with a 20-cm long whip antenna on the posterior end) used for the free-release of juveniles. Dummy and functional transmitters had cylindrical tubes for the passage of harness material. The juveniles tagged in the pilot study had a mean mass of 93 g (range = 87–107 g), and thus transmitters and harness were < 4.3% body weight. We compared four tag attachment methods on juveniles resident in outdoor enclosures (ca. 2 m × 1 m × 0.8 m, LWH) at Orokonui. Each enclosure had a soil substrate, rocks and logs for cover, and artificial burrows made of drainage pipe (Novoflo™) (Mello et al. 2013).

The first method was a "backpack harness" modified from Ussher (1999). Straps made of 6-mm flat elastic were threaded through the cylindrical attachment tubes, then wrapped around the forelimbs in a "figure 8" manner so as to allow the transmitter to sit slightly to one side of the dorsal surface of the animal, just posterior to the neck. Simple stitches (using "Strong Thread," Sullivan's International®) were made to join the elastic straps together where they crossed on the flanks of the animal. The second method ("surgical-tape") used adhesive tape (Leukopor micropore®; 25 mm wide) that was wrapped around the tail twice to secure the transmitter at the base of the tail, just distal to the cloaca, such that the transmitter sat on the side of the tail leaving the antenna to run alongside it. This method has been used for monitoring New Zealand lizards (e.g., *Oligosoma otagense*) (Germano 2007). The third method ("duct-tape") was a variation on the adhesive tape method, instead using duct-tape (initially 3M©, 24 mm wide) that was used and wrapped only once around the tail. Previous research on reptiles has found that duct-tape lasts longer than other types of tape; however, it may cause superficial scars (Wylie et al. 2011). The fourth method was a pelvic harness (hereafter "pelvic attachment") modified from a design used on Great Basin Collared Lizards (*Crotaphytus bicinctores*; J Cossell, pers. comm.). This method involved placing the transmitter on the dorsal surface of the pelvic girdle, where it was secured with round elastic threaded through the tubes then criss-crossed under the ventral surface such that the cloacal vent was not obstructed. Because Tuatara have a gap in the spines dorsal to the pelvis, the transmitter sat securely on the animals and was held firmly in place with a square knot. The backpack harness, surgical-tape, and duct-tape methods were initially tested on one juvenile each for approximately 35 days and the pelvic attachment

FIG. 1. A juvenile Tuatara (*Sphenodon punctatus*) with elastic backpack harness and radio transmitter at five months after release.

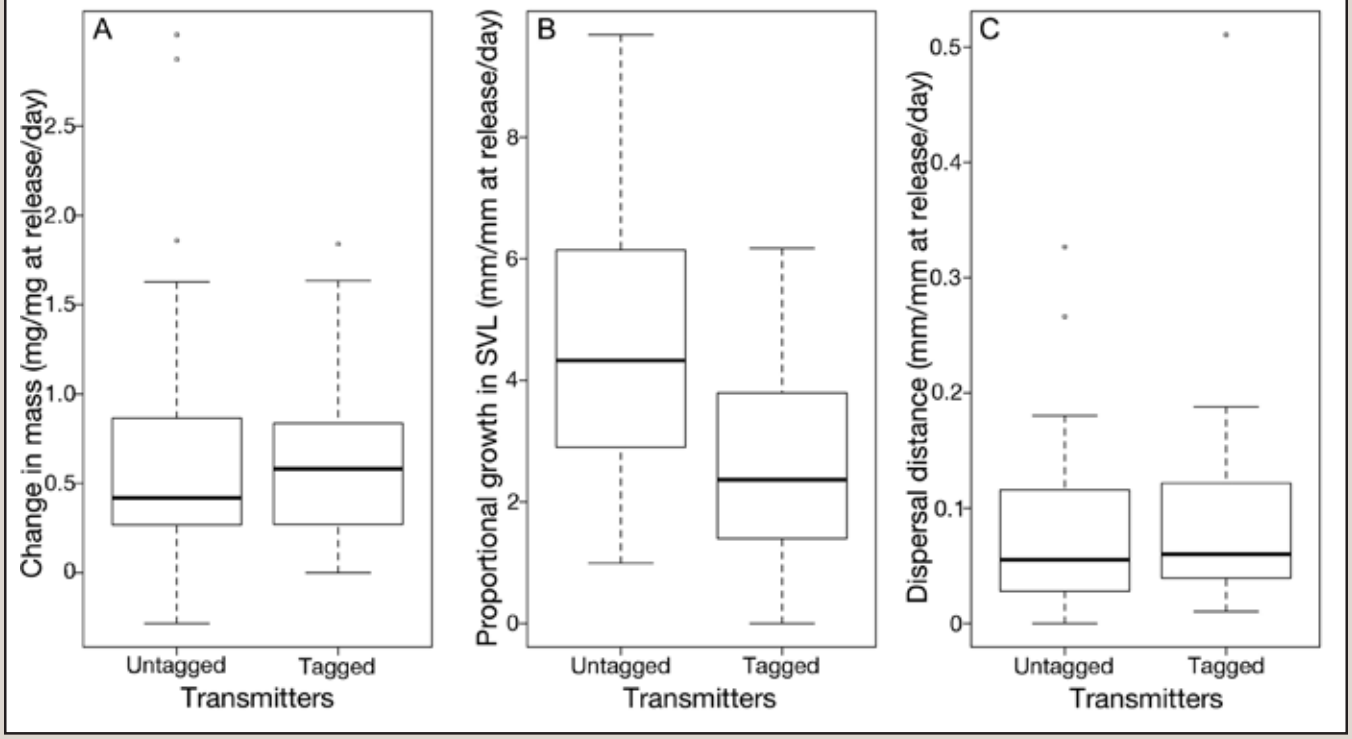

FIG. 2. A comparison of tagged (N = 26) and untagged (N = 29) juvenile Tuatara (*Sphenodon punctatus*) reintroduced to Orokonui Ecosanctuary, South Island, New Zealand: A) change in proportional body mass, B) change in proportional snout–vent length (SVL), and C) dispersal distance corrected for SVL at release. The box shows the median (horizontal bar) and interquartile range; whiskers are 1.5 times the interquartile range and more extreme values are presented outside the whiskers. None of the differences were statistically significant.

method was subsequently tested on two juveniles for 20 days; the pelvic attachment was trialled for a shorter duration due to time constraints.

Pilot study results.—Results from the pilot study showed that the backpack harness remained securely attached; however, it caused minor swelling of the animal's shoulder, which had subsided one month after the harness was removed. By contrast, another juvenile shed the tag that was attached with surgical tape in < 30 days. Initially, the duct-tape method remained attached for < 4 days, but after changing to a more flexible, non-water or UV-resistant tape (Duct-tape II) and wrapping the tape around the tail twice, the attachment stayed on for the remainder of the pilot study (33 days). No injury resulted from the tape methods, and any tape residue was wiped clean with ethanol. Subsequently, the pelvic harness was trialled as we felt that it might offer advantages for Tuatara, including having a more symmetrical placement of the transmitter (better for weight distribution) and possibly less restriction of burrowing; however, juveniles escaped from this attachment in < 4 days. The pilot study informed our decision to use the backpack harness to monitor the translocation of juveniles because of the increased likelihood it would remain attached for the five months of the study, including during molting. We refined this method for the free-release (main study) to try and reduce the possibility of harness-related injury by: 1) using a 3-mm flat elastic (overlocked to reduce elasticity) to permit a better and slightly looser fit of the harness on the juveniles; 2) using a polyester nylon loop threaded through the cylindrical attachment tubes and finished with a square knot to allow elastic straps to be more evenly distributed on the animal; and 3) an additional simple stitch connecting the elastic straps where they crossed on the ventral surface to reduce abrasion by reducing movement of the harness attachment (Fig. 1). Furthermore, we recaptured most tagged juvenile Tuatara at approximately 50-day intervals to check for adverse effects from the harness fit (e.g., skin abrasion and/or swelling).

Main study methods.—The vegetation at the study site for the free-release of juvenile Tuatara comprised mostly regenerating native Kānuka (*Kunzea ericoides*) forest, with remnant patches of podocarp-broadleaved forest (*Coprosma* spp., Lemonwood [*Pittosporum eugenioides*], Mahoe [*Melicytus ramiflorus*], Mapau [*Myrsine australis*]), and modified bush-margins of bracken (*Pteridium* spp.). Juveniles were released in the austral spring, a period of increasing temperature and activity for Tuatara. A total of 14 wild-caught juveniles from Stephens Island (Takapourewa) were released on 17 October 2012. An additional 41 captive-reared juveniles were released on 7 November 2012: 28 from Nga Manu Nature Reserve (hereafter Nga Manu) and 13 from Orokonui. Two more juveniles from Orokonui were released into the same area on 3 December 2012, following completion of additional disease testing. Prior to the free-release of tagged and untagged juveniles, a passive integrated transponder (PIT) tag (11 mm × 2 mm; AVID Identification Systems, Inc., Norco, California, USA) was inserted subcutaneously just anterior to the left rear leg for individual identification. We took several morphometric measurements of juveniles at release and recapture: snout-to-vent length (SVL); vent-to-tail-length; length of the regenerated portion of the tail; and mass. The mass of all juveniles at release ranged from 44–177 g (mean = 93.7 g) and SVL at release ranged from 106–169 mm (mean = 138.9 mm). We attached transmitters onto subsets of the three groups of juveniles: 10 wild-sourced,

TABLE 1. History of telemetry use with Tuatara (*Sphenodon punctatus*) (updated from Ussher 1999).

Adult or juvenile	Attachment	Resident or translocation	Sample size (N)	Period of attachment	Data collected	Negative effects on animals	References
Adult	Surgical tape	Resident (Lady Alice Island)	6	≤ 9 days	Body temperature	Not observed	Tyrrell 2000
Adult	Hind-quarter mount	Resident (Stephens Island)	≤ 4 per trip for 3 trips	≤ 9 days	Body temperature	No data	Barwick 1982
Adult	Backpack	Resident (Stephens Island)	No data	No data	No data	Overloaded animals; entrapment in burrows	Newman 1980
Adult	Backpack	Resident (Taranga Island)	10	≤ 12 months	Habitat use, behavior and body condition	Occasional swollen limbs	L. Anderson, pers. comm., 2013
Adult	Backpack	Resident (Stephens Island)	10	ca. 1 month	Nesting habits	Not observed	J. Moore, pers. comm., 2013
Adult	Backpack	Translocation (Titi Island)	7	ca. 2 months	Dispersal and movements	Not observed	Nelson 1998; N. Nelson, pers. comm., 2013
Adult	Backpack	Translocation (Zealandia™, Wellington)	16	≤ 12 months	Survival, dispersal, and growth	Greater dispersal distances than untagged conspecifics	McKenzie 2007
Adult	Backpack	Translocation (Motohoura Island)	29	≤ 16 months	Dispersal and habitat use	Frequent damage to scales; occasional swollen limbs and broken skin	Ussher 1999
Adult	Backpack	Translocation (Orokonui Ecosanctuary)	10	≤ 4 months	Nesting behavior, body temperature, and dispersal	Occasional damage to scales; occasional swollen limbs and broken skin	A. Besson and S. Adolph, pers. comm., 2013
Adult	Backpack	Translocation (Tiritiri Matangi)	9	< 3 months	Dispersal and habitat use	Occasional swollen limbs	Ruffell 2005
Juvenile	Intraperitoneal implant	Resident (Stephens Island)	4	< 1 month	Movement patterns and habitat use	No data	M. McIntyre, pers. comm., 2013
Juvenile	Backpack	Translocation (Titi Islands)	2	ca. 2 months	Dispersal and movements	Not observed	Nelson 1998; N. Nelson, pers. comm., 2013

10 head-started at Nga Manu, and six head-started at Orokonui. We attempted to match the body size, sex composition (where known), and numbers of individuals in groups as closely as possible. On average, the total package (transmitter and harness) weighed 3.7% of the mass of the released juveniles (range = 2.6–5.4%). All measurements were taken by one author (SJ).

All 26 tagged juveniles were radio-tracked with TR-4 receivers (Telonics, Mesa, Arizona, USA) and hand-held 3-element Yagi folding directional antennas (Sirtrack Electronics, Havelock North, New Zealand) two times per week to minimize disturbance. We removed all transmitters after five months. Untagged juveniles were recaptured opportunistically throughout the duration of the study; only two of the untagged individuals were not recaptured. In addition, we recorded the distance and compass direction of all Tuatara movements. We measured distance (to the nearest cm) using a tape measure and compass direction from the previous sampling point or the release burrow. Distance and direction data were converted to GPS coordinates, relative to several fixed locations at the study site that were established using GNSS technology (Trimble R7 GNSS with Trimble Zephyr™ Geodetic 2 Antenna mounted on a range pole, Sunnyvale, California, USA, with < 3 cm accuracy). GPS coordinates for each animal were then used to calculate post-release dispersal defined as the straight-line distance between the initial release site and final recapture location for Tuatara (measured in ArcGIS 10.1; ESRI, Redlands, California, USA).

Statistical analysis.—We used analysis of variance (ANOVA) to test for effects of transmitters and animal source (i.e., Orokonui, Nga Manu, or Stephens Island) on proportional growth in snout–vent length (mm/mm initial SVL/day), proportional change in body mass (mg/mg initial body mass/day) and proportional dispersal distance (mm/mm initial SVL/day). Data were analyzed using the statistical program "R" (version 3.0.1; R Development Core Team 2013). Statistical significance was assumed at $p < 0.05$. All data satisfied the assumptions of the statistical tests used.

Main study results.—We monitored transmitters attached to 26 reintroduced juveniles for a cumulative total of 3750 animal days (range = 71–158 days per animal). Three juveniles (11.5%) escaped from their harnesses during our study; however, all of these animals were recaptured and had their harnesses replaced within 10 days. There were also three tagged animals (11.5%) recaptured that exhibited skin abrasion and/or swelling of one shoulder and arm; transmitters were removed when this was detected. Harness-induced injury was first noticed ca. four months after release. One tagged individual was found dead at ca. three months post-release, probably as a result of a human-related crush injury that did not occur while radio tracking. Our initial analysis of tagged versus untagged individuals showed that including source population as a factor was not significant in any analysis ($P > 0.05$). Subsequently, we ran our analyses omitting source population; the changes in proportional body mass ($F_{1,53} = 0.252$, $P = 0.618$), proportional growth rates ($F_{1,53} = 1.027$, $P = 0.316$), and dispersal distance ($F_{1,53} = 0.108$, $P = 0.744$) were not significantly different between tagged and untagged juveniles (Fig. 2).

Discussion.—Although radio-telemetry studies require the fundamental assumption that the use of radio tagging does not have a detrimental impact on tagged animals (White and Garrott 1990), many studies, particularly for reptiles, do not quantitatively test this assumption. In our study of reintroduced juvenile Tuatara we used animals that had no transmitters attached as controls. Our results showed that, over the five months post-release, tagging juvenile Tuatara did not negatively impact performance parameters, such as growth, body mass, or dispersal distance. A previous reintroduction of Tuatara to a different site, however, suggested that tagged adults dispersed further than untagged conspecifics, presumably due to disturbance from intensive (daily) monitoring (McKenzie 2007). Dispersal distance, in particular, is a critical issue in reintroduction biology (Armstrong and Seddon 2008), as populations can fail to establish if too many animals disperse far from release areas and are unable to contribute to the breeding population (Le Gouar et al. 2012). The reduced frequency of our monitoring regime, as a result of findings from this earlier study, might have lessened the negative impact of intensive radio-tracking. This illustrates the importance of disseminating post-release data in translocation projects, because while monitoring is important to understand the process of establishment and to improve future programs (Armstrong and Seddon 2008), it should not influence the behavior of released animals.

Our modified backpack harness had no apparent effect on the behavior of juveniles. For instance, we observed tagged juveniles exhibiting the same behaviors as untagged individuals, including foraging and sun-basking. However, one aspect of the welfare of tagged animals that is important to monitor is the presence of harness-induced injury (Millspaugh and Marzluff 2001). In our study three juveniles had skin abrasion and/or swelling of the shoulder and arm; two of these tagged animals had previously escaped their transmitters. It is probable that, when we reattached the harness, the elastic straps were tightened more firmly to prevent future harness loss. This highlights a fine line between having the attachment method too loose, too firm, or just right. Research on lizards has identified similar problems with animals either escaping from the backpack harness (e.g., Fisher and Muth 1995; Price-Rees and Shine 2011) or being injured by this attachment method (e.g., Goodman et al. 2009) despite the duration of monitoring usually being shorter. It should be noted that all of the injured juvenile Tuatara have been recaptured since the transmitters were removed, with the swelling having subsided. Thus, correct fitting and regular visual inspections of animals for abrasions or skin irritations and/or recaptures of tagged animals are important to reduce injuries during the long-term deployment of transmitters, especially when working with growing juveniles.

In summary, we encourage more telemetry studies of reptiles to use comparative data of tagged and untagged animals to evaluate the effects of monitoring, an admittedly difficult task, especially for juveniles due to their cryptic nature and secretive behaviors (Pike et al. 2008). Nevertheless, erroneous conclusions might be reached about the species' ecology, life history, and behavior if tagged animals are not representative of the entire population (White and Garrott 1990; Millspaugh and Marzluff 2001).

Acknowledgments.—For providing the necessary permits, approval, and consultation, we are grateful to the Department of Conservation (permit NM-32559-FAU), the University of Otago Animal Ethics Committee (AEC permit 102-11), Ngāti Koata (kaitiaki of tuatara from Stephens Islands/Takapourewa), and Ngāi Tahu (mana whenua of Otago). We are grateful to Lindsay Anderson, Anne Besson, John Cossell, Jennifer Moore, Nicola Nelson, Mary McIntyre, and Graham Ussher for sharing data on their telemetry studies. This research benefited from the valuable assistance of the following people: Anne Besson, Valerie Fay, Adrian Monks, Jo Monks, Nicola Nelson, Sophie Penniket, Susan Keall, Earl Boyd, Samara Davis, Mike Elkington, Te Hotu Elkington, Pene Gieger, Noela McGregor, Tokotahi

Paul, Te Rangi Walters, Bruce Benseman, Rhys Mills, Laura Bussolini, Luke Easton, Mike Hitchcock, Jenny Kitchin, Alister Robinson, Mel Rivera Rodríguez, Merenia Wright, among others. We are grateful to Orokonui Ecosanctuary personnel, especially Elton Smith and Chris Baillie, for their help and support.

Extracting and Amplifying DNA from Skin Swabs of a Forest Dwelling Tree Frog Species (*Nyctixalus pictus*)

A major contributor to amphibian declines in tropical regions of southeastern Asia is deforestation (Bickford et al. 2010). In Singapore, it is estimated that within the last 200 years, up to 95% of original forest cover has been cleared (Brooks et al. 2003). Despite deforestation, anuran diversity in Singapore is high with almost 30 native species (Baker and Lim 2012) and at least two introduced species (Leong and Lim 2011). Given these high levels of diversity and a recent history of deforestation, Singapore is ideal for genetic investigations of fragmentation effects; however, for forest dwelling species which often have small or dwindling population sizes (Bickford et al. 2010), invasive sampling (i.e., muscle, liver, or toe-clipping) may be counterproductive to conservation management efforts. Thus, we decided to explore the feasibility of using minimally invasive (i.e., non-destructive) sampling to obtain DNA from a vulnerable Singaporean tree frog species.

The phenomenon of global amphibian declines has ushered in a new set of research protocols for performing genetic analyses on endangered and vulnerable species. Many methods for non-destructive sampling techniques have been described. These methods include extracting DNA from buccal swabs (Goldberg et

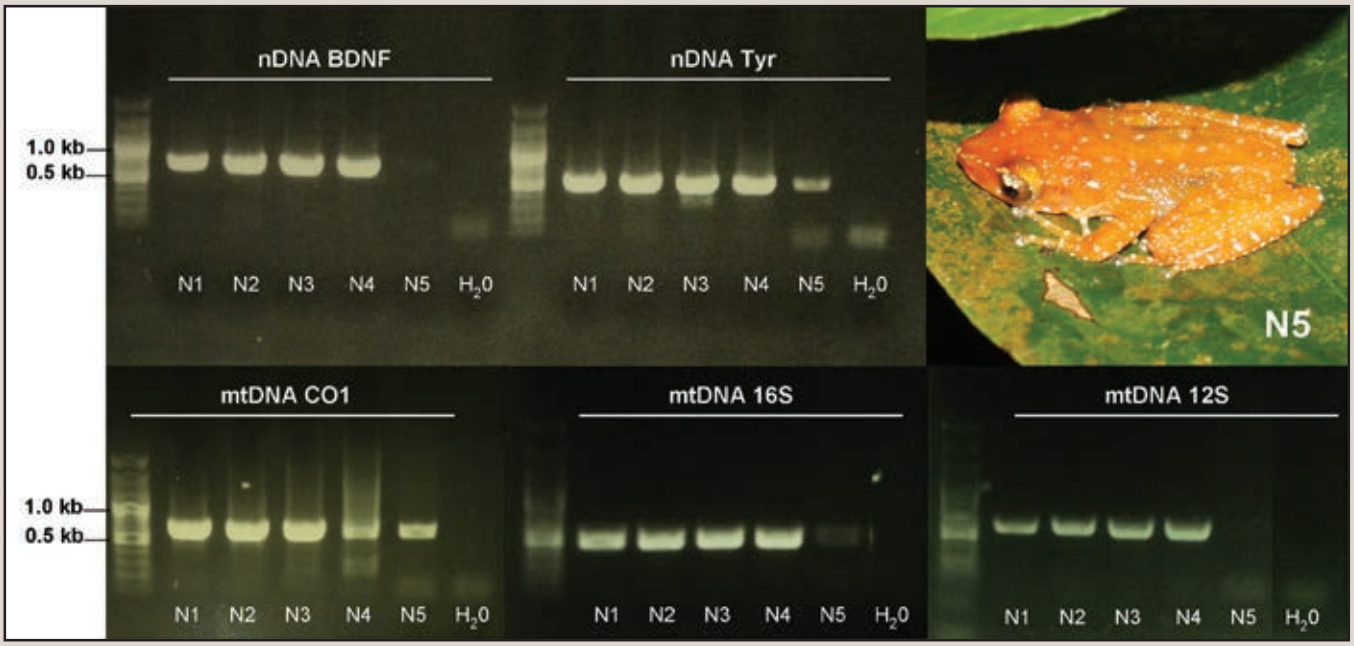

FIG. 1. Successful PCR amplification of two nuclear (nDNA; Brain-derived neurotrophic factor [BDNF] and tyrosinase precursor [Tyr]) and three mitochondrial (mtDNA; 12S and 16S ribosomal subunits [12S & 16S] and cytochrome oxidase I [CO1]) loci from *Nyctixalus pictus* samples from Indonesia, Malaysia, and Singapore. Skin-swabbed adult male specimen of *N. pictus* from the Central Catchment region (N5) is pictured in top right panel.

al. 2003; Pidancier et al. 2003; Broquet et al. 2007), blood (Tapley et al. 2011), and hand or foot swabs (Gallardo et al. 2012). Recently, several studies have successfully employed dorsal and ventral skin swabbing (Mendoza et al., 2012; Prunier et al. 2012; Müller et al. 2013). Given that dorsal and ventral swabbing can be performed quite rapidly while imposing minimal physical restraint, we selected this method for our swabbing protocol. To assess the quality of DNA obtained from this protocol, we attempted to amplify by polymerase chain reaction (PCR) three mitochondrial (mtDNA) and two nuclear (nDNA) gene fragments frequently sequenced from frogs.

Methods.—The Cinnamon Tree Frog (a.k.a. the Spotted Tree Frog), *Nyctixalus pictus* (Anura: Rhacophoridae), is widely distributed throughout the Sunda Shelf region eastward to the Philippines. The combination of a phytotelm breeding ecology and small clutch sizes makes *N. pictus* particularly sensitive to habitat loss. Although considered common by some authorities (e.g., Chua and Lim 2011), the species is listed by the International Union for Conservation of Nature (IUCN) as Near Threatened (Diesmos et al. 2004). Additionally, it is red-listed as Vulnerable in Singapore because it is restricted to the Central Nature Reserves (Baker and Lim 2012). On 21 June 2012 at 2240 h, we located a calling adult male *N. pictus* (Fig. 1) along Old Upper Thompson Road in the Central Catchment Nature Reserve in Singapore (1.38°N, 103.83°E, datum WGS84; elev. 35 m). The individual was captured by hand and swabbed on its dorsal and ventral surfaces (ca. 5–10 times each) using small cotton-tipped swabs. Following this procedure the individual was photographed (Fig. 1) and released. Each swab was placed in a 1.5-mL microcentrifuge tube and transported back to the laboratory.

We stored swabs in the laboratory for ca. 10–15 days at -20°C. Genomic DNA was extracted from swabs using a DNeasy kit (Qiagen) via the same swab-digestion method described in Tupper et al. (2011). For comparison, we also extracted DNA from muscle tissue of four *N. pictus* originating from localities in Malaysia and Indonesia (N1–N4; Table 1). Swab and muscle samples were eluted in 40 and 200 µL of Buffer AE, respectively. Voucher specimens corresponding to samples N1–N4 are housed at the Raffles Museum for Biodiversity Research (RMBR) at the National University of Singapore. To quantify amount of double-stranded DNA we isolated from each sample, we used a Qubit® fluorometer (Invitrogen, Life Technologies). We used a high-sensitivity assay kit in all Qubit® trials. PCR trials were performed using previously published "universal anuran" primers for two nDNA (BDNF and Tyrosinase; de Sá et al. 2012) and three mtDNA (12S and 16S ribosomal subunit genes [12S and 16S]; cytochrome oxidase I [CO1]; Streicher et al. 2009) gene fragments. PCRs were performed in 20-µL reactions that included: 11.9 µL of DEPC water, 2 µL of 5X reaction buffer, 2 µL of dNTPs (2 mM each), 2 µL of primers (1 µL forward primer + 1 µL reverse primer; each 10 µM concentration), 0.1 µL of Dream Taq DNA Polymerase (5 unit/µL; Thermo Scientific), and 2 µL of extracted DNA. We used previously described thermal cycling profiles for each primer set (see Streicher et al. 2009; de Sá et al. 2012). After PCR experiments, amplicons were visualized using 1–2% agarose gels stained with ethidium bromide or SYBR® Safe DNA stain (Life Technologies).

Because we were limited to sampling a single individual of *N. pictus* for this study, we conducted a second study using a frog species from North America to demonstrate the repeatability of our protocol. This validation study used skin swabs of *Hyla arenicolor* (Anura: Hylidae) from the southwestern United States. We extracted DNA from dried muscle (H1) and skin swabs (H2–H4) from frogs sampled at localities in the states of Texas and Arizona (Table 1). We tested two mtDNA primer sets (16S and CO1) and one nDNA primer set (BDNF) on the samples of *H. arenicolor* using the same laboratory protocols described above for *N. pictus*.

Results.—The skin swab DNA extraction (sample N5) had detectable amounts of double-stranded DNA (0.053 ng/µL; Table 1) but, not surprisingly, far less than any muscle tissue samples

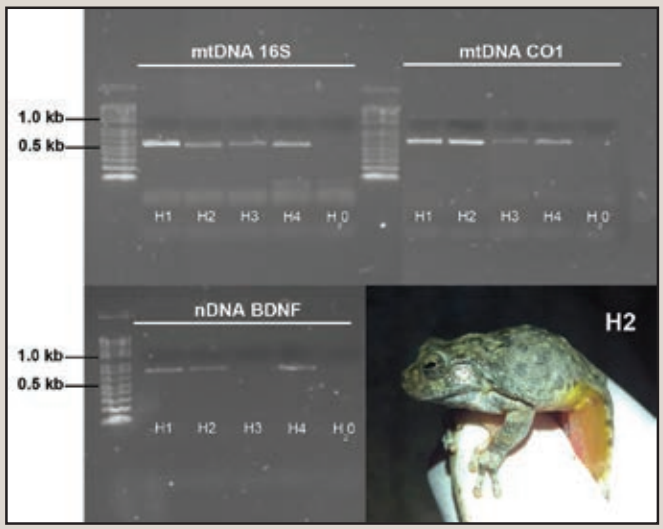

FIG. 2. Successful PCR amplification of one nuclear (nDNA; Brain-derived neurotrophic factor [BDNF]) and two mitochondrial (mtDNA; 16S ribosomal subunit [16S] and cytochrome oxidase I [CO1]) loci from *Hyla arenicolor* samples from the United States. Skin-swabbed adult of *H. arenicolor* from Arizona (H2) is pictured in bottom right panel.

(17.8 to >150 ng/µL; Table 1). PCR amplifications were successful with visible bands in all samples, although substantially less efficient in the skin swab sample (Fig. 1). Notably, the BDNF and 12S experiments produced only small levels of amplification for the N5 sample (Fig. 1). In our study of *H. arenicolor* we found that the dried muscle sample (H1) possessed similar amounts of double-stranded DNA as the fresh swabs (0.15–0.82 ng/µL; Table 1). The mtDNA and nDNA primer set amplified gene fragments across all individuals with the exception of BDNF for sample H3 (Fig. 2). The size of amplicons (in number of base pairs [bp]) matched our expectations for each locus based on previous studies (Streicher et al. 2009; de Sá et al. 2012): BDNF (ca. 700 bp), Tyr (ca. 550 bp), 12S (ca. 500 bp), 16S (ca. 650 bp), and CO1 (ca. 680 bp).

Discussion.—Overall, our ability to successfully amplify several mtDNA and nDNA markers from skin swab samples is a promising result towards feasibility of using this methodology more widely. Although success is not surprising given the known efficacy of this technique (Prunier et al. 2012), it is interesting that the amplification of all five loci was effective enough for amplicons to be visible on an agarose gel despite a very small amount of DNA template (smaller by at least two orders of magnitude than most previous studies; e.g., Müller et al. 2013). However, demonstrating that we can amplify multiple genetic markers from skin swabs of *N. pictus* comes with at least one caveat. Skin swabbing has also been shown to feature inter-individual contamination from when frogs presumably slough epithelial cells onto one another through amplectant or territorial interactions (Müller et al. 2013). While this is not an issue for investigations concerned with deeper relationships (e.g., molecular systematics and phylogeography), population genetics studies may suffer from this limitation. Although we recognize that liver, muscle, and toe-clip samples will typically yield more DNA template, under circumstances when non-destructive sampling must often be used (e.g., conservation priority forest-dwelling frogs from Singapore), our findings are an encouraging reminder that very little template DNA is needed to amplify nDNA and mtDNA markers for genetic analysis.

Acknowledgments.—All research activities in Singapore were conducted under NParks permits to JWS, DJJN, DPB (NP/RP12-025). We thank Jeremy Woon Ren Wei for assistance with acquiring research permits. We thank Chui Ho Man and Tay Soon Lian for assistance with access to the Central Catchment Nature Reserve. JWS is indebted to Alison Wee for her assistance with laboratory work at NUS. We thank Adeline Seah for discussion and Matt Fujita for laboratory access. Fieldwork was conducted in Texas and Arizona under permits SPR-0707-1387 (TX Parks and Wildlife) and SP612813 (AZ Game and Fish Dept.), respectively. Samples were collected in the USA under UTA IACUC protocol A08.025 to Carl Franklin, Jonathan Campbell, Eric Smith, and JWS. We thank Jessica Maxcy and Carl Franklin for assistance with fieldwork in the USA. This project was funded in part by a National Science Foundation EAPSI grant to JWS (OISE-1209793).

Extremely Low Prevalence of *Batrachochytrium dendrobatidis* Infection in Eastern Hellbenders (*Cryptobranchus alleganiensis alleganiensis*) in Southwest Virginia, USA

The large, fully aquatic Eastern Hellbender (*Cryptobranchus alleganiensis alleganiensis*) is a phylogenetically unique member of North America's salamander diversity and a focus of increasing conservation concern. Substantial population declines have been reported across much of the Eastern Hellbender's range (Wheeler et al. 2003; Foster et al. 2009; Burgmeier et al. 2011b), and this subspecies is now apparently extirpated from some historical localities (Graham et al. 2011). Exact causes for population declines are unclear, although habitat degradation is often suspected to play a significant role (Wheeler et al. 2003; Foster et al. 2009; Graham et al. 2011). Recently, however, studies have documented *Batrachochytrium dendrobatidis* (*Bd*) infection in both captive and wild hellbender populations (Briggler et al. 2007; Briggler et al. 2008; Gonynor et al. 2011; Bodinof et al. 2012; Regester et al. 2012; Tominaga et al. 2013). This fungal pathogen has been detected on hellbender museum specimens collected as far back as 1969 (Bodinof et al. 2011). *Bd* causes the devastating amphibian disease chytridiomycosis (Berger et al. 1998; Kilpatrick et al. 2010; Eskew and Todd 2013), and evidence from the tropics suggests that disease-driven amphibian declines may have wide-ranging effects on ecosystem functioning in lotic systems (Whiles et al. 2006). However, the prevalence of *Bd* in river- and stream-associated amphibians from temperate latitudes is understudied; the limited data currently available suggests that *Bd* infection is at relatively low prevalence in low-order stream systems in the US (Hossack et al. 2010).

Although many studies suggest that wild hellbenders do not typically manifest clinical symptoms of chytridiomycosis or suffer mortality from the disease (Gonynor et al. 2011; Souza et al. 2012; Tominaga et al. 2013), there is at least one report of hellbender mortality associated with chytridiomycosis (Bodinof et al. 2012). In addition, even if chytridiomycosis rarely causes hellbender mortality in isolation, *Bd* infection might still negatively affect hellbender populations by allowing for detrimental co-infections (Bodinof et al. 2011) or through interactions with other stressors such as habitat alteration (Hopkins and DuRant 2011). In at least some systems, however, the relationship between *Bd* prevalence and habitat disturbance is counterintuitive, with the highest infection risk occurring in the most pristine habitats (Becker and Zamudio 2011). Therefore, we sought to evaluate *Bd* prevalence in Eastern Hellbenders occupying a single stream predominately surrounded by forest but with a gradient of surrounding habitat disturbance. We also report *Bd* infection status of another fully aquatic salamander, the Common Mudpuppy (*Necturus maculosus*), captured incidentally during our study.

We sampled 14 different stream reaches across a 57-km expanse of a single stream (3rd–4th order) within the Tennessee River Basin of southwest Virginia, USA where hellbenders are known to be relatively abundant (Hopkins and DuRant 2011). The name and location of the stream is withheld because of the sensitive conservation status of our study species in Virginia. The watershed is predominately forested (65–76% forest cover across our sampling range), but progressive encroachment of agricultural activity, suburban development, and increased road density pose threats to downstream habitat quality and generate a disturbance gradient within the watershed. For additional information on a subset of the study reaches, including data on land use within the watershed, see Hopkins and DuRant (2011).

Sampling occurred in the summer months between 27 June 2011 and 2 September 2011, and between 9 July 2012 and 6 September 2012. The sex of adult hellbenders is distinguishable at this time due to the swollen cloacae of males. We located animals during visual encounter searches by lifting and searching beneath large rocks while snorkeling. After capture, we swabbed hellbenders and incidentally captured Common Mudpuppies for *Bd* by rubbing a single cotton-tipped swab five times over the dorsal and ventral surfaces, five times on each side, and five times on each foot for a total of 40 swabs per animal. We used disposable vinyl gloves when swabbing animals. We stored swabs in 70% ethanol at room temperature until extractions took place.

We isolated DNA following the swab extraction protocol of Retallick et al. (2006) with the exception that we removed ethanol from swabs by placing them on a heat block at 55°C until all standing ethanol was evaporated (approximately 48 h). To detect *Bd* DNA, we used the real-time PCR assay described by Boyle et al. (2004). We ran samples on a Step-One Plus Real-time PCR machine (Applied Biosystems, Foster City, California) using the "Presence/Absence" mode as we were only interested in *Bd* prevalence within the hellbender population. For real-time PCR, we used 2.5 µl of diluted DNA in a total reaction volume of 12.5 µl. We ran samples singly (Kriger et al. 2006), and included positive (100 zoospore equivalent *Bd* standards) and negative (molecular-grade water) controls on all plates. All positive and negative controls behaved as expected, producing no false negatives or false positives. To validate our laboratory methods, we also ran seven samples collected in August 2013 from a *Bd*-positive captive population of hellbenders (Virginia Dept. of Game and Inland Fisheries, unpubl. data); results obtained using our methodology (one *Bd* positive hellbender out of seven tested) corresponded with those independently generated by Virginia state biologists.

A total of 230 unique individual hellbenders, 113 from 2011 (76 adults, 37 juveniles) and 117 from 2012 (103 adults, 14 juveniles), were captured and swabbed for *Bd* infection during our study. Captured hellbenders averaged 36.81 ± 0.57 (mean ± SE) cm in total length, 23.81 ± 0.37 cm in snout–vent length (SVL), and 337.30 ± 14.25 g in mass. Only a single hellbender collected in 2011 tested positive for *Bd*, resulting in a prevalence of 0.88% that year. The sample from this individual was re-run and again tested positive, further confirming *Bd* presence. The positive individual was an adult male captured on 11 July 2011 in apparently good condition in a stream reach lying in the middle of the sampled watershed and thus in the middle of the habitat gradient described above and in Hopkins and DuRant (2011). A total of 76 other individuals were sampled from this stream reach in 2011; these samples all tested negative. All hellbenders sampled in 2012 tested negative for *Bd* infection. A total of six Common Mudpuppies were incidentally captured and swabbed during sampling events in 2012. Captured mudpuppies averaged 21.63 ± 1.14 (mean ± SE) cm in total length, 14.52 ± 0.80 cm SVL, and 48.33 ± 7.62 g in mass. All mudpuppies tested negative for *Bd*.

Overall, our study suggests there was an extremely low prevalence of *Bd* infection within an Eastern Hellbender population in southwest Virginia at the time animals were sampled. Only a single hellbender of 230 sampled during the summers of 2011 and 2012 tested positive for *Bd*. The low overall prevalence of *Bd* precluded us from making any general inferences about factors (e.g., age/size, sex, surrounding land use) that might influence *Bd* prevalence in this hellbender population. However, it is important to note that the stream reaches examined in this study are all predominately forested and lack major industrial inputs, and even the most disturbed reaches of this study system have not yet experienced the level of habitat degradation of some other historical hellbender habitats. Thus, sampling across a larger range of stream habitat quality might provide greater insight as to whether anthropogenic factors influence *Bd* prevalence in hellbender populations. Although our sample size for Common Mudpuppies was small, our report of *Bd* absence in this species mirrors the result of Ouellet et al. (2005) who also failed to find evidence of infection in 12 individuals of this species collected from Québec, Canada. However, *Bd* infection has been reported from other fully aquatic *Necturus* species collected in Florida and Louisiana (Chatfield et al. 2012), and more comprehensive studies are needed to elucidate *Bd* infection dynamics in this salamander genus.

Prior reports of *Bd* prevalence within hellbender populations have found the pathogen to be common in some populations (within-population prevalence of approximately 20–50%; see Gonynor et al. 2011; Souza et al. 2012; Tominaga et al. 2013) but rare in others (1.3% prevalence in Burgmeier et al. 2011a). Our results are similar to several other studies of stream-associated salamanders that also found low prevalence of *Bd* (summarized in Hossack et al. 2010). Hossack et al. (2010) hypothesized that their findings of low *Bd* prevalence in many North American stream-associated amphibians might be driven by seasonally cold in-stream temperatures that limit *Bd* growth during cooler winter months. Optimal temperatures for the growth of *Bd* range from 17–25°C (Piotrowski et al. 2004). In our stream system in Virginia, water temperatures are cold (< 6–8°C) during winter months, but at the time we sampled animals, water temperatures typically exceeded the lower limit for optimal *Bd* growth (average during surveys = 18.6 ± 0.3°C; range 14.5–22.0°C). Thus, the low prevalence of *Bd* infection in hellbenders in the present study could partially reflect an inability of *Bd* to thrive in areas that experience suboptimal, cold winter temperatures. However, in light of the fact that other streams throughout the hellbender's range likely have comparable winter temperatures but *Bd* can be prevalent in these systems (Gonynor et al. 2011; Souza et al. 2012; Tominaga et al. 2013), other factors related to surrounding land use, in-stream habitat quality, pollution, community assemblage, and the general health of hellbenders are more likely determinants of *Bd* prevalence that deserve further investigation.

The results of this study add to our basic understanding of the prevalence of *Bd* infection in hellbender populations in one of the remnant strongholds within the range of this imperiled amphibian species. The extremely low prevalence of *Bd* reported here and elsewhere (Burgmeier et al. 2011a), contrasts with the higher prevalence of *Bd* infections in other hellbender populations (Gonynor et al. 2011; Souza et al. 2012; Tominaga et al. 2013). It remains unclear whether *Bd* infections regularly result in disease (chytridiomycosis) in wild hellbenders to a degree that negatively affects hellbender health, reproduction, and survival. However, chytridiomycosis has been a problem in captive populations and may have caused mortality in at least one translocated animal (Bodinof et al. 2012). Broader spatial and temporal monitoring is needed to fully assess the risk that *Bd* poses to wild hellbender populations and to facilitate the early detection and mitigation of any potential chytridiomycosis outbreaks in this unique freshwater amphibian. Additionally, the recent description of another pathogenic fungus, *Batrachochytrium salamandrivorans* (*Bs*), that can cause lethal chytridiomycosis in northwestern European salamanders suggests that pathogen surveillance efforts focused solely on *Bd* may underestimate the threat of fungal disease (Martel et al. 2013). Consequently, future work should use newly developed molecular methods that enable the simultaneous detection of both pathogens in amphibian host populations (Blooi et al. 2013).

Acknowledgments.—We thank J. Foley and S. Worth for assistance with equipment and techniques related to the molecular assay for *Bd*. Field assistance was provided by S. DuRant, B. Hopkins, M. Hepner, C. Bodinof Jachowski, M. Pinder, A. Wilson, D. Drewitt, and

S. Bone. C. Bodinof Jachowski provided comments that improved the paper. Field work for this project was conducted under VDGIF collecting permit 035981 and complied with Virginia Tech IACUC protocols 08-085 and 11-140. Batrachochytrium dendrobatidis in Virginia Amphibians: Within and Among Site Variation in Infection

Substantial variation in the presence and intensity of *Batrachochytrium dendrobatidis* (*Bd*) infection exists among individuals, populations and species of amphibians (Muths et al. 2008; Knapp et al. 2011; Lannoo et al. 2011; Raffel et al. 2010; Savage et al. 2011). While the factors contributing to this variation are numerous and complex, environmental conditions such as temperature and moisture appear to play a key role in shaping *Bd*'s interactions with its amphibian hosts. Moisture is necessary for infection to occur and essential for the spread of the disease, since the infective zoospore stage is aquatic (Berger et al. 2005; Longcore et al. 1999). The pathogen can grow across a wide range of temperatures (4–28°C), with some variation among isolates (Stevenson et al. 2013), but the optimal range for growth is between 13 and 25°C (Piotrowski et al. 2004).

Due to the physiological limitations of *Bd*, more arid habitats and habitats with temperatures outside the thermal optimum of *Bd* often pose lower risk for amphibian infection (Muths et al. 2008; Forrest and Schlaepfer 2011; Lannoo et al. 2011). Prevalence of the disease can also fluctuate seasonally with changes in temperature and/or precipitation (Berger et al. 2004; Retallick et al. 2004; Kriger and Hero 2006; Russell et al. 2010; Forrest and Schlaepfer 2011; Lannoo et al. 2011; Savage et al. 2011). Thus, the external environment may pose important constraints on infection (e.g., Longo et al. 2010; Pullen et al. 2010), along with any natural amphibian defenses against *Bd* (reviewed by Rollins-Smith and Woodhams 2012).

In eastern North America, where we completed our study, *Bd* has been detected in at least 48 species of amphibians (of 92 tested; Appendix I) and has been present in the region since at least the 1960s (Ouellet et al. 2005). In this region, as elsewhere, the prevalence of *Bd* varies both temporally and spatially. Temporal changes in this region are associated with seasonal variation in temperature (Longcore et al. 2007; Lannoo et al. 2011; Brannelly et al. 2012), as winter temperatures fall below the thermal optimum for *Bd*, and summer temperatures rise above it. Temperature also appears to play a role in spatial variation, with cooler, shaded ponds having the highest infection intensities in early summer (Raffel et al. 2010). However, variation in the species composition of the amphibian community among sites may also contribute to spatial variation in infection. For example, Richards-Hrdlicka et al. (2013) found that the presence of ranids, and in particular Green Frogs (*Lithobates clamitans*), was associated with a higher prevalence of *Bd*.

In this study, we characterized variation in the presence and intensity of *Bd* infection in four species of amphibians commonly encountered in Virginia, USA: Eastern Newts (*Notophthalmus viridescens viridescens*), American Bullfrogs (*Lithobates catesbeianus*), Spring Peepers (*Pseudacris crucifer*), and American Toads (*Anaxyrus americanus*). Prior studies suggest that although *Bd* may be widespread in Virginia, prevalence tends to be low for the focal species in our study (newts: 11%, peepers: 0–23%, bullfrogs: 0–8%, and toads: 6–17%; Pullen et al. 2010; Davidson and Chambers 2011; Goodman and Ararso 2012) as well as for other Virginia amphibians (Hossack et al. 2010; Pullen et al. 2010; Gratwicke et al. 2011).

We collected data on *Bd* infection for a total of 355 amphibians (Table 1) using skin swabbing, which is an effective, nonlethal method for detecting *Bd* infection in amphibians (Hyatt et al. 2007). In April–June of 2010, we swabbed adult newts at three sites (N = 7–27 per site) and, in August 2010, we swabbed juvenile bullfrogs at one site (N = 61). In March–May 2012, we swabbed adult newts at one site (N = 15), adult toads at three sites (N = 9–16 per site), adult peepers at ten sites (N = 7–19 per site), and juvenile and adult bullfrogs at four sites (N = 9–14 per site; Table 1). The bullfrogs varied substantially in size, and represented both juveniles and adults, so we also examined the relationship between *Bd* infection and snout–vent length (SVL) in bullfrogs. In 2012, for Spring Peepers, we recorded water temperature at three sites in each pond near where individuals were calling to examine the relationship between *Bd* infection and water temperature at the time of sampling (between 2000 and 2300 h). These three measurements were averaged for analyses.

Amphibians were caught with a dipnet or by hand, using new nitrile gloves for each individual. All individuals were swabbed immediately or placed in a sterile Whirl-Pak bag or plastic container until swabbing could take place (within ~1 h of capture). Before swabbing, we rinsed all amphibians to remove any dirt and transient bacteria, as we were collecting data on the amphibians' cutaneous microbial communities for other studies. In 2010, we rinsed bullfrogs and newts by placing them in 50-ml plastic containers filled with 25 ml of sterile, deionized water, and repeated this rinse twice for each individual. In 2012, we rinsed all species by pouring 50 ml (peepers, toads, and juvenile bullfrogs) or 100 ml (adult bullfrogs) of sterile, deionized water over their bodies, in part to accommodate the large size of many of the frogs. We used sterile rayon swabs for all collections (MW113, Medical Wire Equipment & Co. Ltd., Corsham, UK). Histological examinations of infection in two species of frogs have found that infections are generally concentrated in the forelimbs, hindlimbs, and ventral surface of the abdomen (Berger et al. 2005; Puschendorf and Bolaños 2006); thus, for all frogs, we swabbed the ventral surface 20 times, each thigh 5 times, and each hind foot 5 times for a total of 40 strokes (similar to Hyatt et al. 2007). We swabbed newts in a similar manner, except we swabbed each lateral surface 5 times instead of the thighs. We placed swabs in sterile, empty 1.5 ml microcentrifuge tubes on ice in the field and transferred them in the laboratory to –20°C or –80°C for storage.

DNA was extracted from swabs using the Qiagen DNeasy Blood & Tissue Kit (Qiagen, Inc., Valencia, CA, USA). We followed the manufacturer's Quick-Start protocol, with the following

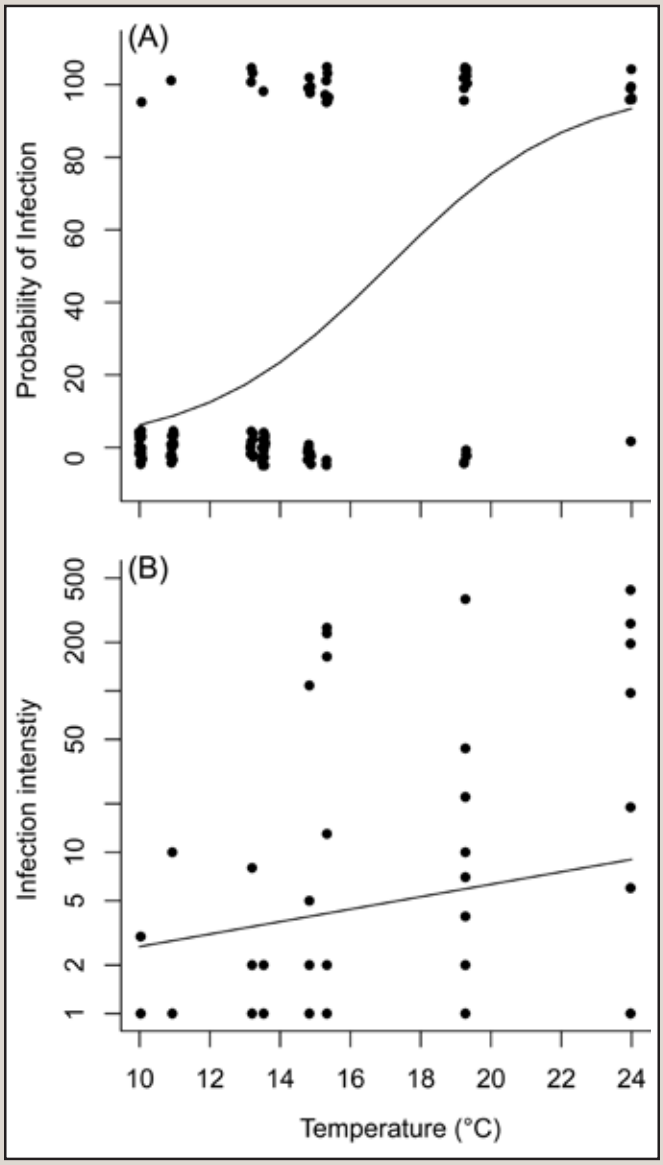

FIG. 1. Relationship between *Batrachochytrium dendrobatidis* infection and pond water temperature for Spring Peepers (*Pseudacris crucifer*) in the spring of 2012. Data in (A) indicate individual infection status of Spring Peepers (points are jittered slightly so that all points are visible). Data in (B) are individual infection intensities, shown on a log scale. Temperatures are the mean pond water temperature determined at the time of sampling for each locality. Uninfected individuals are shown but were not included in analyses of infection intensity. Lines are predictions of generalized linear mixed models.

modifications: 1) we skipped Step 1, which pertains to other types of samples (e.g., tissue, blood, or cultured cells), and instead added 180 µl lysis buffer solution (20 mg lysozyme/1 ml lysis buffer) to each tube and incubated at 37°C for 1 h; and 2) for Step 2, we added 25 µl proteinase K to each reaction in addition to 200 µl buffer AL and incubated at 70°C for 30 min. Our final elution volume was 100 µl.

To quantify amphibian *Bd* infection, we used a quantitative, real-time PCR (qPCR) assay developed by Boyle et al. (2004). Each run included a negative control as well as a series of five dilution standards ranging in concentration by an order of magnitude from 0.1 to 1000 zoospore equivalents. *Bd* strain JEL404, from northeastern North America, was used to create the standards (ITS copy number per zoospore = 39; Longo et al. 2013). Samples were initially run in singlicate (Kriger et al. 2006); however, positive samples were rerun 1–2 more times to confirm the consistency of results and more accurately estimate infection intensity. Standards were always run in triplicate. To confirm that inhibition was not affecting amplification, an internal positive control (Taqman Exogenous Internal Positive Control reagents, Applied Biosystems, Foster City, CA, USA; Hyatt et al. 2007) was added to several randomly selected samples from each species (N = 5 newts, 6 bullfrogs [2 from 3 sites], 6 peepers [3 from 2 sites], and 6 toads). The positive control was added to one of the three triplicate reactions for each of these samples. We considered samples with 0.0 values to be negative for the presence of *Bd* and all other samples positive (as in Briggs et al. 2010). To obtain a relative measure of the intensity of *Bd* infection across individuals, we used the mean number of zoospore genomic equivalents detected in qPCR assays (Kriger et al. 2007).

All analyses were run in R v. 3.0.2 (R Core Team 2013). We estimated disease prevalence as the proportion of individuals that tested positive for *Bd* infection out of the total number of individuals sampled at a given site, calculated separately for each species. We calculated 95% confidence intervals based on a binomial distribution for all prevalence estimates using the Wilson Interval (package binom; Dorai-Raj 2009). We calculated site-level infection intensity as the mean infection intensity of all infected individuals at a site. Bootstrap confidence intervals were calculated for site-level intensity estimates for all sites with sufficient variation in individual infection intensity (> 1 infected individual; method = BC_a, package boot; Davison and Hinkley 1997; Canty and Ripley 2013).

We tested for variation in infection across sites, temperatures, and body size with the various datasets outlined below. We used generalized linear models for analyses of intraspecific variation among sites (GLM; package MASS; Venables and Ripley 2002) and generalized linear mixed models for all other analyses (GLMM; package lme4; Bates et al. 2013). In the GLMMs, we included "site" as a random effect to account for nestedness of individuals sampled at the same site. This approach is analogous to linear regression, except that it utilizes a more generalized form of linear regression that has been developed to accommodate non-normal data such as binary or count data. Our response variables in all analyses were individual infection status (infected or not, testing for differences in the probability of an individual being infected among groups) or infection intensity (infection level based on zoospore equivalents, excluding uninfected individuals). Analyses of infection status were made using an underlying binomial distribution and logit function, and analyses of infection intensity were made using an underlying negative binomial distribution and log function.

First, to assess variation in infection among sampling sites, we compared infection status and infection intensity of peepers, newts, and bullfrogs across all sites where these species were sampled (2010 newts sampled at three sites, 2012 peepers sampled at nine sites, and 2012 bullfrogs sampled at four sites; each species analyzed separately). Second, to assess variation in infection with temperature, we tested for relationships between infection status or infection intensity and pond water temperature using the data we collected for Spring Peepers in 2012. Finally, to assess how infection levels vary across the size range of sampled individuals, we tested for a relationship between infection status or infection intensity and SVL using the data we collected on

TABLE 1. Levels of *Batrachochytrium dendrobatidis* infection, summarized by sampling event, in Eastern Newts (*Notophthalmus viridescens viridescens*), American Bullfrogs (*Lithobates catesbeianus*), Spring Peepers (*Pseudacris crucifer*), and American Toads (*Anaxyrus americanus*). Prevalence is given as the proportion of individuals infected at each site and infection intensity as the mean infection intensity of all infected individuals. Upper and lower confidence intervals, in parentheses, are 95% Wilson and Bootstrap (BCa) for prevalence and infection intensity, respectively. Bootstrap confidence intervals were not calculated for sites with insufficient variation in infection intensity.

bullfrogs (four sites in 2012). All Spring Peeper analyses excluded two sites—Airport Pond and Kentland Farm Pond—where all individuals were uninfected. Toads were also not analyzed because they were all uninfected.

All of the species we swabbed, except American Toads, were infected at multiple sites. Prevalence of infection, including all sampling localities and years, ranged from 25–91% in newts, 46–92% in bullfrogs, and 0–86% in peepers (Table 1). We found infected newts and bullfrogs at every locality we sampled (3 and 4 sites, respectively), although the probability of being infected varied among sampling sites (GLM; newts: $\chi^2_{2,45} = 18.8$, $P < 0.0001$, bullfrogs: $\chi^2_{3,44} = 8.3$, $P = 0.04$). For peepers, we also found that the probability of being infected varied across sites (GLM; $\chi^2_{7,103} = 45.3$, $P < 0.0001$). Two of the 10 sites we sampled had no infection (Airport and Kentland Farm Ponds in Blacksburg, Virginia; these were not included in the analysis).

Among the three species with some level of infection, we observed the highest infection levels in peepers (range: 0–421 zoospore equivalents), followed by bullfrogs (0–236 zoospore equivalents), and newts (0–211 zoospore equivalents) (Table 1). Low levels of infection were common, particularly in bullfrogs and newts. At sites where *Bd* was present, infection intensity differed among sites for all three species (GLMM; bullfrogs: $\chi^2_{3,31} = 20.0$, $P = 0.0002$, newts: $\chi^2_{2,21} = 13.6$, $P = 0.001$, peepers: $\chi^2_{7,26} = 9.0$, $P = 0.01$).

Pond water temperature ranged from 10–24°C across 2012 Spring Peeper sampling events across the eight sites with some infection (Fig. 1). Water temperature explained variation in infection status of Spring Peepers (GLMM; $\chi^2_1 = 15.7$, $P < 0.0001$; Fig. 1A), as well as infection intensity (GLMM; $\chi^2_1 = 5.9$, $P = 0.02$; Fig. 1B). Specifically, we found the highest probabilities and intensities of infection at sites with higher temperatures.

Bullfrogs ranged from 3.8–19.7 cm SVL. All sizes of bullfrogs were equally likely to be infected (GLMM; $\chi^2_1 = 3.2$, $P = 0.07$), and infection intensity was relatively low across all sizes of individuals (excluding uninfected individuals; GLMM; $\chi^2_1 = 1.4$, $P = 0.2$). However, individuals larger than ~10 cm always had minimal infections (0–1 zoospore equivalent; N = 7).

Similar to other recent studies from eastern North America (Raffel et al. 2010; Richards-Hrdlicka et al. 2013; Appendix I), we found considerable variation in the likelihood and intensity of *Bd* infection among sites. In addition, we report some of the highest prevalences of *Bd* found thus far in Virginia (but see Pullen et al. 2010). There are likely several factors contributing to the high incidence of *Bd* we found. First, the combination of swabbing and Boyle et al.'s (2004) qPCR assay that we used to detect infection is generally considered to be more sensitive than other approaches, which can miss low levels of infection (< 10 zoospore equivalents; Hyatt et al. 2007; Kriger et al. 2006). Second, we concentrated our sampling efforts during the time of year when *Bd* infection is most prevalent in the region (Longcore et al. 2007; Lannoo et al. 2010; Pullen et al. 2010).

Our survey of the literature found that *Bd* has been detected in a little over half of the amphibian species tested in the eastern U.S., including approximately 61% of frogs and 47% of salamanders (Appendix I). Most genera of frogs and salamanders appear to have at least some susceptible and some resistant members (i.e., *Bd* infection detected versus no infection detected), although sample sizes for a number of apparently resistant species are low and therefore inconclusive (Appendix I). *Bd* has been detected previously in all four species included in the present study; however, not all studies that have sampled these species have found infection. For example, while we found *Bd*-infected Spring Peepers in 8 of the 10 sites we surveyed and in 34 out of 143 total individuals, in prior surveys infection has only been documented in this species in three out of 10 states, and in only 20 of 206 total individuals (Appendix I).

In Spring Peepers, we found that the probability of infection was related to pond water temperature. Much of the variation in temperature is likely attributable to variation in sampling date, as it warmed over the course of the breeding season and sampling. This suggests that many peepers may begin the breeding season with little or no active infection, but that prevalence and infection intensity may change relatively rapidly as temperatures warm to favor *Bd* growth. However, it is important to note that while we considered temperature here because of the prior links that have been demonstrated between *Bd* and temperature (Longcore et al. 2007; Raffel et al. 2010; Lannoo et al. 2011), other factors that change over the course of the breeding season could also play a role. For example, infection levels in a population of breeding males might increase over the course of the breeding season due to increased opportunities for transmission and reinfection. In addition, several of the ponds we sampled later in the spring of 2012 were on the coastal plain of Virginia where it would be consistently warmer than in the mountains, where our other sites were located. The one exception to this pattern was a mountainous site, Sylvatica Pond, at Mountain Lake Biological Station (Table 1). It was the last site we sampled in 2012, but temperatures were still very cool and infection was lower than at the coastal plains sites that were sampled a few days before.

Infection was common in bullfrogs and newts at all of the sites we sampled in early spring. The high prevalence of *Bd* we found during this time corroborates other studies from eastern North America (Ouellet et al. 2005; Longcore et al. 2007; Pullen et al. 2010; Lannoo et al. 2011; Brannelly et al. 2012). However, all three of these studies report a decline in prevalence during the summer, whereas we found that more than half of juvenile bullfrogs sampled in late summer at Mountain Lake Biological Station were infected. At just over 1100 m, this was our highest-elevation site. Although our data are limited, this result is intriguing because it suggests that changes in risk of *Bd* infection associated with variation in environmental conditions along elevational gradients may occur in eastern North America, similar to those in other parts of the world (Berger et al. 2004; Woodhams and Alford 2005; Muths et al. 2008; see also Rollins et al. 2013). Specifically, risk may be greater for populations at higher elevations if pond water temperatures stay cool and favor growth of the pathogen for longer periods of time in comparison to lower elevations.

We found no infection in American Toads at any of our three sampling sites, which is interesting given that several other studies have found infection in this species (Longcore et al. 2007; Davidson and Chambers 2011; Richards-Hrdlicka et al. 2013). The absence of infection in the individuals we sampled could be indicative of resistance in the populations we studied. Alternatively, it may be an artifact of the time during which this species was sampled—just as they were emerging from winter hibernation to breed. Overwintering in terrestrial habitat has been associated with reduced prevalence of infection (i.e., relative to species that overwinter in aquatic habitat; Longcore et al. 2007). This might also partially explain why we found very little infection in Spring Peepers when they first began to appear at breeding ponds.

All of the sites that we sampled contained both infected and uninfected individuals, indicating factors within a pond may

contribute to intraspecific variation in the presence and intensity of *Bd* infection. Of the multiple factors that could potentially interact with infection rates, we believe that size, age, or developmental stage may be important. For example, a study of *Rana boylii* by Lowe (2009) found that *Bd* infection was absent in adults, although present in individuals less than 41 mm. Our data suggest that larger bullfrogs also typically have minimal, if any, infection. Unfortunately, these findings are difficult to compare to previous work because, although many studies have included bullfrogs in their sampling, few report the sizes of bullfrogs sampled (Rothermal et al. 2008; Schloegel et al. 2009; Davidson and Chambers 2011; Goodman and Ararso 2012; Richards-Hrdlicka et al. 2013). Other factors not addressed by this study that may differentially limit infection among individuals include variation in the responses of the animals' immune systems, in the disease-fighting function of the symbiotic microbial communities living on their skin, or in their thermoregulatory behavior (Richards-Zawacki 2009; Rollins-Smith and Woodhams 2012; Rowley and Alford 2013).

This study highlights interesting variation in *Bd* infection in four species of temperate amphibians and offers valuable insight into how disease dynamics may unfold in early spring in eastern North America. Importantly, while we found *Bd* infection to be more common in Virginia than previously thought, none of the animals we encountered during this study had high infections or showed clinical signs of the disease (Hughey, Becker, and Walke, pers. obs.). There are several possible reasons. First, seasonal fluctuations in temperature, including decreases in temperature below the thermal optimum of *Bd* during winter, are probably an important check on *Bd* growth and thus its impact on its hosts. Second, the species we studied may possess critical immune or microbial defenses against *Bd* infection. Third, the strains of *Bd* present in Virginia may be less virulent. Additional studies are needed to develop a more integrative understanding of the complex set of factors contributing to patterns of infection and disease in these and other species.

Acknowledgments.—We thank P. Shirk, J. Vonesh, J. Wyderko, and S. Zemmer for assistance in the field and P. Sattler at Liberty University and G. Eaton at Claytor Nature Study Center for recommending sites in Lynchburg and Bedford, respectively. Funding was provided by the Morris Animal Foundation and the National Science Foundation (DEB-1136640). This research was conducted with approval from Virginia Tech's Institution Animal Care and Use Committee (protocols 08-042-BIOL, 10-029-BIOL, and 12-040-BIOL) and with permission from the Virginia Department of Game and Inland Fisheries (permits 44303 and 38862).

Appendix I. List of amphibian species from eastern North America that have been tested for *Bd* infection. We conducted a thorough survey of the literature to create a list of the species of amphibians present in eastern North America have been tested for Bd infection, and of those, which species have tested positive. We included information from the following states: Alabama (AL), Arkansas (AR), Connecticut (CT), Florida (FL), Georgia (GA), Kentucky (KY). Louisiana (LA), Maine (ME), Maryland (MD), Massachusetts (MA), Mississippi (MS), New Jersey (NJ), New York (NY), North Carolina (NC), Ohio (OH), Pennsylvania (PA), South Carolina (SC), Tennessee (TN), and Virginia (VA). In addition, we included one study containing data from eastern Canada. No data were available for Delaware, New Hampshire, Rhode Island, West Virginia, or Vermont. Studies were included only if we could obtain information about sample size, the number of infected individuals, and the state in which study was conducted. Samples representing hybrids or that were not identified to species were not included.

Frogs	Total	Infected	State (States with *Bd*-infected individuals in **BOLD**)	Source
Bd detected (N = 20 species)				
Acris crepitans	515	101	**AR**, GA, **LA**, SC, **VA, OH**	Daszak et al. 2005, Pullen et al. 2010, Goodman & Ararso 2012, Hill et al. 2011, Rothermal et al. 2008, Timpe et al. 2008, Steiner & Lehtinen 2008
Acris gryllus	117	6	**FL**, GA, SC	Daszak et al. 2005, Rizkalla et al. 2009, Rizkalla et al. 2010, Rothermal et al. 2008, Timpe et al. 2008

First Report of *Batrachochytrium dendrobatidis* Associated with Amphibians in Kansas, USA

Determining the distribution of infectious disease agents such as *Batrachochytrium dendrobatidis* (*Bd*), the pathogenic fungus that causes chytridiomycosis, is important for understanding disease patterns and transmission in populations. In the USA, *Bd* has been broadly sampled and detected throughout most regions (46 of 50 states; *Bd*-maps.net; Gaudreau et al. 2010; Richards-Hrdlicka et al. 2013) with the exception of the northern and central Great Plains region including Kansas. In northeastern Kansas, sampling in 2007 did not detect the occurrence of *Bd* (Steiner and Lehtinen 2008). Failure to detect *Bd* in the state may be due to insufficient survey. Alternatively, it may be due to transmission factors that reduce occurrence including temperatures >25°C that may assist hosts in clearing *Bd* infections (Woodhams et al. 2003) or low human population densities that limit the transfer and reduce the effects of the pathogen in the region (Kriger and Hero 2009; Lane and Burgin 2008). Recent modeling based on global sampling of *Bd* (3,733 sites) predicted low likelihood of the occurrence of *Bd* in the northern and central Great Plains region including the state of Kansas (Olson et al. 2013), thus supporting the hypothesis that amphibians inhabiting the drier interior of the USA may be at less risk of *Bd* (Lannoo et al. 2011). To address this distributional gap of *Bd* in the USA, we surveyed amphibians of south-central Kansas with three objectives: 1) detection or lack of detection of *Bd* in Kansas amphibian populations; 2) comparison of *Bd* infection rates in lotic and lentic habitats; and 3) comparison of *Bd* infection rates in urban and non-urban locations.

Sampling was conducted 10 July 2012, 11 July 2013, and 16–17 August 2013 in south-central Kansas (Sedgwick and Kingman Counties; Fig. 1). Locations were selected to investigate potential impacts of abiotic and micro-habitat variables on *Bd* infection rates in amphibian populations. Each location (Ninnescah Reserve, Gerber Reserve, and Chisholm Creek Park; Fig. 1) included two habitats (lotic/lentic) approximately 500 m apart. Ninnescah Reserve (Ninnescah River 37.5398°N, 97.6790°W, 394 m elev. / pond 37.5369°N, 97.6773°W, 397 m elev.) and Gerber Reserve (Smoots Creek 37.6765°N, 97.9463°W, 439 m elev. / pond 37.6796°N, 97.9476°W, 439 m elev.) are non-urban locations in the Ninnescah River drainage; Chisholm Creek Park (Chisholm Creek 37.7429°N, 97.2704°W, 410 m elev. / pond 37.7422°N, 97.2644°W, 412 m elev.) is an urban location in the Arkansas River drainage. Both drainages are part of the Lower Arkansas watershed. Land use surrounding the locations is primarily non-urban rangeland (Gerber Reserve), non-urban farmland (Ninnescah Reserve), and urban city-center (Chisholm Creek Park). GPS coordinates, air temperature, water pH, and water

FIG. 1. Locations where anurans were sampled in Kansas, USA. Prior to the present study, *Bd* was not detected in the state. Map (upper left) of USA showing states with *Batrachochytrium dendrobatidis* (*Bd*) detected (brown), undetected (white; Kansas), and not surveyed (green). Map (upper right) of central USA showing south-central counties in Kansas (circumscribed in red) that we surveyed. Survey locations and river drainages in Kansas (lower inset) showing *Bd* prevalence per location (red = % detected, blue = % undetected). Map generated using ArcMap 10 (ESRI 2011).

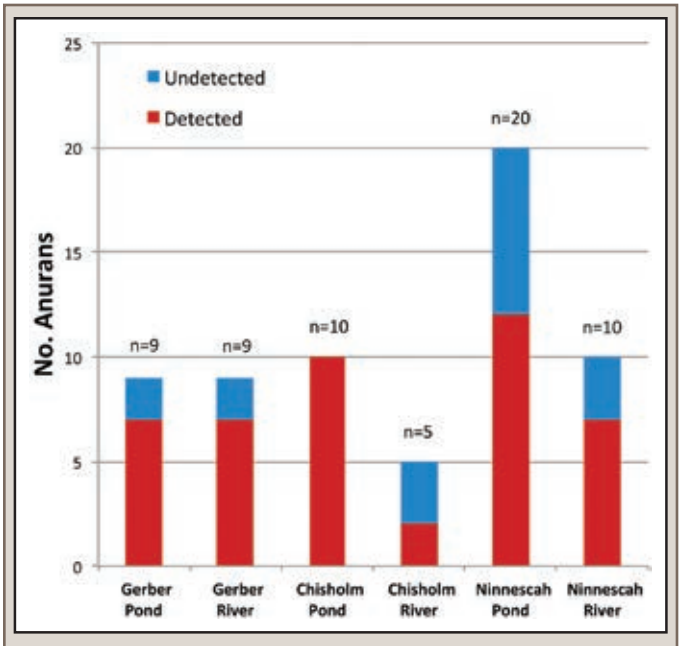

FIG. 2. Prevalence of *Batrachochytrium dendrobatidis (Bd)* detected in anurans at sampling locations (Gerber = Gerber Reserve, Chisholm = Chisholm Creek Park, Ninnescah = Ninnescah Reserve) and sampling habitats (pond = lotic, river = lentic) in Kansas, USA.

temperature were recorded for each site. Anurans were collected within the site, handled using sterile methods, and sampled using standard techniques (Brem et al. 2007). All individuals were image-vouchered (see http://ninnescahlife.wichita.edu). A slight teratological deformity in one distal appendage was observed (see http://ninnescahlife.wichita.edu/node/583); no behavioral abnormalities were observed. Swabs were stored in individually labeled screw cap microcentrifuge tube vials without alcohol at –20°C until analysis. DNA from each swab was extracted using two extraction protocols: Bond's (2013) protocol was used in 2012 and a slightly modified HotSHOT protocol (Truett et al. 2000) was used in 2013. After extraction, a slightly modified version of Annis' (2004) protocol was used, followed by gel electrophoresis. Detection of *Bd* was based on a 300-bp band and a positive control. PCR was conducted in triplicate (2013) or duplicate (2012); if *Bd* was detected for a sample in two of the replicates, the corresponding animal was considered *Bd* positive.

A total of 62 anurans were sampled, with 45 individuals testing positive for presence of *Bd* (72.6%; Table 1). *Bd* was detected in >60% of individuals tested at all three survey locations and at both lotic and lentic habitats within each location (Fig. 2, Table 2). Notably, *Bd* was present in two separate river systems, the Arkansas and Ninnescah River drainages, and in both urban (Chisholm Creek Park) and non-urban (Ninnescah Field Station, Gerber Reserve) localities.

TABLE 1. *Batrachochytrium dendrobatidis* (*Bd*) detected per anuran species sampled in Kansas, USA.

Species	No. *Bd* detected	N	% *Bd* detected
Acris blanchardi	30	41	73.2
Anaxyrus woodhousii	6	11	54.5
Lithobates blairi	7	8	87.5
Lithobates catesbeianus	1	1	100
Undetermined larva	1	1	100
Total	45	62	72.6

TABLE 2. *Batrachochytrium dendrobatidis* (*Bd*) detected by survey location (Ninnescah and Gerber = non-urban; Chisholm = urban), habitat (lotic = pond, lentic = river), and anuran species sampled in Kansas, USA.

Habitat	Location	Species	No. *Bd* detected	N	% *Bd* detected
Lotic	Ninnescah	*Acris blanchardi*	5	7	71.4
		Anaxyrus woodhousii	6	11	54.5
		Lithobates blairi	1	2	50.0
	Chisholm	*Acris blanchardi*	2	5	40.0
	Gerber	*Acris blanchardi*	4	5	80.0
		Lithobates blairi	2	2	100.0
		Lithobates catesbeianus	1	1	100.0
	Total		21	33	63.6
Lentic	Ninnescah	*Acris blanchardi*	3	6	50.0
		Lithobates blairi	4	4	100.0
	Chisholm	*Acris blanchardi*	10	10	100.0
	Gerber	*Acris blanchardi*	6	8	75.0
		Undetermined larva	1	1	100.0
	Total		24	29	82.8

Our sampling represented 4 of 11 anuran species that are distributed in south-central Kansas (Collins et al. 2010), with Blanchard's Cricket Frogs (*Acris blanchardi*) comprising the majority (66.1%) of sampled individuals. For each of the four species (*Acris blanchardi, Anaxyrus woodhousii, Lithobates blairi, Lithobates catesbeianus*), *Bd* was detected in > 54% of individuals sampled. The high percentage of *Bd*-positive bullfrogs is the result of a low sample size (N = 1). One unidentified frog larva was also sampled and tested positive for presence of *Bd*.

We compared amphibian populations at six sites and three locations in south-central Kansas, and our sampling regime detected a high prevalence of *Bd* in all anuran species in urban and non-urban locations as well as in pond and stream habitats. Furthermore, species susceptibility to infection in our survey is consistent with known data (Blaustein et al. 2005). Our results contradict an earlier Kansas survey conducted in 2007 (Steiner and Lehtinen 2008). Their study sampled 5 individuals of *Acris blanchardi* associated with a pond habitat in a non-urban area of Jefferson County (northeastern Kansas) and did not detect *Bd*. In contrast, the diversity of habitats in which we document *Bd* infection, in combination with detection in all surrounding states, make it likely that this pathogen occurs throughout Kansas.

When we initiated our research, it seemed plausible that our sampling would not detect the occurrence of *Bd* due to a lack of detection in 2007 (Steiner and Lehtinen 2008), modeling that predicted low likelihood of *Bd* occurrence in the northern and central Great Plains region (Olson et al. 2013), and numerous additional biotic and abiotic factors. For example, temperatures and arid conditions are major determinants affecting *Bd* virulence and the effects of *Bd* in amphibians (Berger et al. 2004; Woodhams et al. 2003). High ambient temperatures (air and water) are correlated with lower *Bd* infection rates and desiccation of zoospores as well (Gaertner et al. 2012; Johnson et al. 2003; Lannoo et al. 2011). This is relevant because our sampling took place at mid-summer when temperatures were high (lotic habitats 24–25°C; lentic habitats 26–28°C; air temperature 25–30.5°C) and during an extreme drought in 2012. Additionally, survey locations in rural Kansas where habitats are less disturbed may have avoided introduction of *Bd* (Lannoo et al. 2011). In spite of these factors we detected a high prevalence of *Bd* associated with anurans in south-central Kansas. Rather than lack of occurrence of *Bd* in the north and central Great Plains region, our data support the hypothesis that *Bd* is endemic and insufficiently surveyed in the region.

Acknowledgments.—We are grateful to the Wichita State University Reserves and Wichita Great Plains Nature Center for access to field sites. We thank the following individuals for assistance in development and direction of this study: Wichita State University Field Ecology Students (2011–2013), Dede H. Olson, Kathryn Ronnenberg, Joe Mendelson, Jim Mason, Linda Trueb, Emily Brown, Leland F. Russell, and Kit Bond. All animals were handled in compliance with and with approval provided by State of

Kansas Wildlife Permit #SC-133-2013. This is contribution number 22 of the Wichita State University Ninnescah Biological Station.

Detection of Ranavirus in Archival Specimens

The decline of amphibian populations worldwide has garnered considerable attention over the past two decades resulting in the identification of multiple contributing factors. Pathogens, particularly ranaviruses, have been considered among the leading causes of mass mortality in larval amphibians (Green et al. 2002; Daszak et al. 2003). In recent years ranaviruses have been detected in several locations in Ohio, USA (Homan et al. 2013). How long ranaviruses have been in Ohio is an important question, the answer to which offers insight into the impact, persistence, and spread of ranaviruses within a region. Here I report the detection of ranavirus infection in archival specimens collected in northeast Ohio in 1999 the earliest published record of ranavirus infection in Marbled Salamanders (*Ambystoma opacum*) in Ohio.

ROBERTA L. MUEHLHEIM
The Cleveland Museum of Natural History,
Department of Vertebrate Zoology,
1 Wade Oval, University Circle, Cleveland, Ohio 44106, USA
e-mail: rmuehlhe@cmnh.org

The eggs of a single *A. opacum* female were collected from a small moist depression adjacent to a vernal pool located within Indian Point Park that is part of the Lake Metroparks system in September 1999. Three species of *Ambystoma* salamander are known to use this pond for breeding: *A. opacum, A. maculatum, A. jeffersonianum* and *Ambystoma* unisexuals. Amphibians of this pond have been the subject of long-term monitoring beginning with a drift fence study from 1993 to 2002 (Quinn and Matson 2011) followed by subsequent seasonal inspections. Steady declines in population size of all salamander taxa in this pond, as a result of limited recruitment, have been documented but the cause(s) has yet to be determined (Quinn and Matson 2011).

The egg clutch was reared to metamorphosis in a laboratory at the Cleveland Museum of Natural History. Six metamorphosed animals were retained in captivity in isolation from other animals in three separate collections. Animals were housed in pairs as follows: two remained in the museum laboratory and the other four were kept in two separate private collections. The *A. opacum* were housed in pairs at each location. Diets were composed of wild-caught invertebrates such as earthworms, crickets, slugs,

spiders, and store-bought crickets. Animals thrived, appearing healthy and robust, and developed normally until approximately two years of age. The onset of symptoms was consistent among all animals. Initial symptoms were similar, marked by lethargy and cessation of appetite, while later stage infection was defined by accelerated/excessive skin shedding, skin ulcerations, and necrosis of the tissue surrounding digits that resulted in bone exposure. These last two symptoms are characteristic of the ulcerative skin syndrome disease of ranavirus reported by Teacher (2002). Illness progressed rapidly and ended in death 7–12 days from the onset of symptoms. Ranavirus was not initially considered as a disease agent and veterinary diagnoses were inconclusive. Upon death, three specimens, including one from each collection, were fixed in formalin, preserved in 70% ethanol and installed in the Herpetological Collection of the Cleveland Museum of Natural History. Post-mortem examination of animals showed pale enlarged livers that were very fragile and granular in texture. All animals exhibited wart-like lesions on the stomach surface and two animals had lesions extending onto the surface of the small intestine.

The development of new techniques for extracting genetic information from formalin-fixed specimens (Kattenbelt et al. 2000) initiated the testing of the three archival specimens (all female) for ranavirus infection in 2011. Tissue samples from the liver, pancreas, and kidneys were collected and sent for analysis to Research Associates Laboratories, Dallas, Texas. Animals were tested for ranavirus and chytrid fungus, *Batrachochytrium dendrobatidis*. Ranavirus was confirmed using a SYBR green-based Real-time PCR assay. Primers and probes are the property of Research Associates Laboratories (pers. comm., 2014). Each sample was run for 40 cycles and followed by melting curve analysis to assess the specificity of qPCR reaction. Samples were tested a minimum of six times each against known positive and negative controls. All animals tested positive for ranavirus DNA with C_t (cycle threshold) levels between 34 and 37. All samples were negative for chytrid fungus.

The C_t values for these animals indicate a low amount of target nucleic acid in the sample (Rothermel et al. 2013). These values, however, may not be meaningful regarding viral load since these are formalin-fixed archival specimens that are likely to have had some degree of DNA degradation (Kattenbelt et al. 2000).

The results suggest that ranavirus was present in one Ohio pond since at least 1999, assuming that the eggs were infected at the time of collection. Embryos might have been infected horizontally, although vertical or pseudovertical transmission is also possible. Vertical and pseudovertical transmission of ranavirus was suggested by Dufus et al. (2008) in eggs from a pair of wild-collected Wood Frogs (*Lithobates [Rana] sylvaticus*) in which the male and one embryo tested positive. Although no obvious source of contamination can be identified, it is possible that the three *Ambystoma* were infected while in captivity. The concurrent onset of disease in three separate facilities might argue against the possibility of exposure to ranavirus as adults; however, it would explain the two-year period without symptoms followed by disease onset and death. This would place the date of ranavirus in Ohio in 2001. In either case it appears that viruses in the genus *Ranavirus* have been in Ohio at least a decade before the first published report (Homan et al. 2013).

Swabber Effect: Swabbing Technique Affects the Detectability of *Batrachochytrium dendrobatidis*

The chytrid fungus, *Batrachochytrium dendrobatidis* (*Bd*) has been implicated in amphibian declines in numerous amphibian populations around the world (Lötters et al. 2010). The pathogenic fungus infects the mouthparts of larval anurans, and the skin of adult amphibians, and this may lead to mortality of the host (Berger et al. 1998; Voyles et al. 2011). Quantitative PCR analysis is a widely used technique for estimating the prevalence of *Bd* infection in wild frog populations (Kriger et al. 2006a; 2006b; 2007; Hyatt et al. 2007). Numerous sampling methods, such as bathing (Hyatt et al. 2007), toe clipping (Boyle et al. 2004; Hyatt et al. 2007) and swabbing (Kriger et al. 2006a; Hyatt et al. 2007) have been used to obtain *Bd* samples from amphibians. The swabbing technique is preferred over other sampling techniques as it is highly sensitive, can easily be applied in the field, and meets ethical standards as it is a non-invasive technique (Kriger et al. 2006b; Hyatt et al. 2007). This technique has been used extensively for comparing *Bd* prevalence among populations (e.g., Kriger and Hero 2007a; Kriger et al. 2007; Van Sluys and Hero 2009).

To our knowledge, there have been no studies examining the influence of swabbing effort for estimating the prevalence of *Bd* infection in anuran populations. This is despite evidence from non-diseased related ecological field studies that show increased survey effort results in higher probability of detecting species (Field et al. 2002; de Solla et al. 2005). Similarly, the effect of observer can additionally influence outcomes of ecological surveys with results often differing between observers (Morin and Conant 1994; Thompson and Mapstone 1997; Cunningham et al. 1999; Diefenbach et al. 2003). Similar effects are seen in the microbial field, where studies have shown particular methods for detecting microbes (i.e., *E. coli*) may not work in particular climates or on particular microbes due to variation in detection methods (Scott et al. 2002). With numerous *Bd* studies being conducted worldwide, it is imperative to evaluate if there is an influence of different swabbers (individual humans) on estimates of *Bd* prevalence.

Herein, we compare *Bd* prevalence estimates between two swabbers to evaluate whether bias is caused by individuals when comparing *Bd* prevalence. We also examine the influence of repeated swabbing on *Bd* prevalence estimates. A well-studied site for the presence of *Bd* was chosen within Numinbah Valley, south-east Queensland, Australia (28.178° S, 153.228° E). We surveyed male *Litoria wilcoxii* (Anura: Hylidae) for the presence of *Bd* zoospores one night in early October, 2007, as it is known that prevalence of *Bd* is highest at this time of year for the study site (Kriger and Hero 2007b).

Two individuals (designated Swabber 'A' and Swabber 'B') swabbed sixty-seven male frogs. Swabber A had several years of experience in *Bd* swabbing while Swabber B had only previously swabbed for *Bd* in one *L. wilcoxii* population. Each frog was swabbed ten times over the ventral surface of the posterior thighs, ten times over both lateral sides of the frog (from groin to armpit), ten times over the ventral surface and five outward strokes on the webbing of both feet (Kriger et al. 2006a), totaling 60 strokes per frog per swabber (see Youtube video "How to swab a frog for chytrid fungus": http://www.youtube.com/watch?v=Ip-urLMLK9k). Sampling alternated between who swabbed first and who swabbed second. In total, 33 *Litoria wilcoxii* were swabbed first by Swabber 'A', followed by Swabber 'B'; and 34 frogs were swabbed first by Swabber 'B', then by Swabber 'A'. All frogs were caught and handled with 250 mm × 200 mm plastic bags which were discarded after a single use to avoid *Bd* transfer and sample contamination. To ensure the same frog was not sampled twice, frogs were not released until all swabbing had been completed. Swabs were stored on ice until return to the laboratory, where they were kept frozen to maintain *Bd* zoospore DNA from degradation (Van Sluys et al. 2008).

Swabs were analyzed for *Bd* presence using quantitative (real-time) PCR techniques as described by Boyle et al. (2004) with the changes recommended by Kriger et al. (2006b). After successful singlicate runs, machine failure occurred and samples were lost during the triplicate analysis. Therefore, only the singlicate method was used to determine positive or negative samples. The use of the singlicate method is valid for *Bd* prevalence, with no significant loss of prevalence accuracy occurring between triplicate and singlicate methods (Kriger et al. 2006b). A Z-test was used to determine if there was a significant difference in *Bd* prevalence between swabbers and swabbing order.

Overall, 17 of 67 (25.4%) frogs were *Bd*-positive (Table 1). There was a significant effect of swabber on *Bd* detection ($Z = 2.281$; $p = 0.023$) with Swabber 'A' detecting *Bd* on 16 of 17 (94.1%) *Bd*-positive frogs and Swabber 'B' detecting *Bd* on 11 of 17 (64.7%) *Bd*-positive frogs. Of the 67 total frogs sampled, Swabber A detected *Bd* on 23.9% and Swabber B detected *Bd* on 16.4%. Swabber 'B' detected *Bd* on one frog that Swabber 'A' failed to detect, despite Swabber 'A' detecting *Bd* on more frogs.

Ten of 17 (58.8%) *Bd*-positive frogs yielded positive results on both first and second swabbing events (Table 1). Of the 7 frogs on which *Bd* was detected by only one swabbing event, the first swabbing tended to detect *Bd* more often, on 5 frogs, while the second swabbing uniquely detected *Bd* on 2 frogs. There was no significant effect of repeated swabbing on *Bd* prevalence ($Z = 1.301$; $p = 0.193$).

Overall, researchers can be confident that a significant proportion of *Bd*-infected frogs will be detected during repeated swabbing events because we found that there was no significant difference in *Bd* prevalence between the first and second swabbing events. This may be important for monitoring changes in prevalence over short time periods. Additionally, this means

TABLE 1. Number of swabs that tested positive for *Batrachochytrium dendrobatidis* (*Bd*) for two swabbers, A and B, during two swabbing events. Prevalence detected by first, second, and both swabbers is presented for number of *Bd*-positive swabs and for the total population sampled.

	Bd detected by		
	only first swabber	only second swabber	both swabbers
Swabber A	4	2	10
Swabber B	1	0	10
Total Positive Swabs	5	2	10
Prevalence (%) for *Bd*-positive frogs (N = 17)	29.4	11.8	58.8
Prevalence (%) for total population (N = 67)	7.5	3.0	14.9

that there is a significant chance that *Bd* will be detected if a frog needs to be swabbed more than once (e.g., due to swabbing error on the first swabbing event).

The significant difference between the researchers conducting the swabbing is important as the swabber can significantly influence the prevalence estimates for the population sampled. Several positive frogs were missed by Swabber 'B', resulting in false negatives. This may be critical when managing captive husbandry populations, especially where threatened species are housed. We recommend that frogs in captivity are swabbed/sampled more than once, preferably by different swabbers, to improve confidence of *Bd* detection. It is also recommended that swabbers have 'swabbing training' prior to swabbing within captive populations.

Why was there a significant difference in *Bd* detection between swabbers? Studies have shown that experienced researchers can obtain different results when compared with inexperienced researchers (Fitzpatrick et al. 2009). Therefore, different levels of swabbing experience between Swabber 'A' and Swabber 'B' may have contributed towards different *Bd* detection levels. The lack of experience by Swabber 'B' may have resulted in the swabbing technique being inadvertently modified (i.e., a slight change in swabbing locations) or a different application of the same methodology (i.e., a decrease in swabbing pressure), which may have resulted in lower *Bd* detection. Therefore, where different swabbers are involved, comparisons of *Bd* prevalence must be undertaken with caution. Further experimentation is required to elucidate these hypotheses.

There are currently numerous swabbing methodologies in use for sampling *Bd* (e.g., Boyle 2004; Kriger et al. 2006a; Hyatt et al. 2007; Schloegal et al. 2009; Hunter et al. 2010; Simpkins et al. 2010; Vredenburg et al. 2011). Most swabbing methods target specific areas of the frog's body (i.e., ventral surface, thighs, feet) that are known to be highly susceptible to *Bd* infection (Berger and Speare 1998). Alternatively, some studies only target a limited area of the frogs body surface (e.g., Schloegal et al. 2009) potentially missing *Bd* infected areas that could produce false absences. Studies use a different number of strokes per frog (e.g., 60 for Kriger et al. 2006a and 30 for Vredenburg et al. 2011) which may influence the likelihood of *Bd* detection through increased swabbing effort. While the effect of 'swabber' would be difficult to control, our results highlight the importance of having a consistent swabbing technique that could be followed by all researchers to maximize the chance of obtaining comparable data. Comparable *Bd* data could help determine the influence of various environmental variables on *Bd* from studies conducted by different researches worldwide (Lötters et al. 2010).

It is logistically impossible to control for the effect of swabbing individuals when comparison of studies from different locations are being made. However, our study demonstrates the importance that individual swabbers can have on *Bd* detection and it is imperative that swabbing methodologies be standardized to allow for comparisons of results.

Acknowledgments.—Funding was provided by the Eppley Foundation for Research, and the Endangered Frog Research Group at Griffith University. Jon Shuker, Katrin Lowe, Diana Virkki, and Johan Gustafson assisted with catching the male *Litoria wilcoxii* in the field. We thank the anonymous reviewers for improving this manuscript.

Detection of *Batrachochytrium dendrobatidis* in the Eastern Spadefoot, *Scaphiopus holbrookii*, at Cape Cod National Seashore, Barnstable County, Massachusetts, USA

The pathogenic fungus *Batrachochytrium dendrobatidis* (*Bd*) has contributed to the global decline of amphibians (Young et al. 2007) and is widely known for its prevalence in certain anuran populations (Weinstein 2009). Although *Bd* is more commonly associated with permanent-pond-dwelling frogs (Kriger and Hero 2007), it has also been implicated in die-offs of terrestrial toads such as the Boreal Toad (*Anaxyrus boreas*; Muths et al. 2003; Deguise and Richardson 2009), Yosemite Toad (*Anaxyrus canorus*; Green and Sherman 2001), Common Toad (*Bufo bufo*; Garner et al. 2005), and Midwife Toad (*Alytes obstetricans*; Garner et al. 2005). Recently, *Bd* was also documented at Cape Cod National Seashore (Barnstable County, Massachusetts, USA) in a road-killed specimen of another terrestrial species, the Eastern Spadefoot (*Scaphiopus holbrookii*; Tupper et al. 2011). Because *S. holbrookii* are uncommon and protected throughout southern New England (Klemens 1993; Cook 2005), additional data on *Bd* prevalence are important to the successful conservation of this species. Therefore, the goal of this project was to further quantify rates of *Bd* occurrence in *S. holbrookii* at Cape Cod National Seashore.

Using Google Earth version 6 (www.googleearth.com), we divided the Provincelands (a region of the Cape Cod National Seashore where *S. holbrookii* are most common; Fig. 1; see Tupper et al. [2007] for a more detailed description of the site) into three sampling regions: an east, central and west region. We established separate sampling routes (based on established trails that meandered through dunes and cranberry bogs) within each sampling region to avoid oversampling within a given area of the Provincelands. Each route was sampled weekly. Sampling began within 60 min after sunset and ended by 0200 h. Samples were collected between 1 June and 8 August 2011 and 2013. To assay for *Bd* presence, *S. holbrookii* skin surfaces were thoroughly sampled (using methods described by Hyatt et al. [2007]) with sterile dry swabs (no. MW113, Medical Wire and Equipment Company, Durham, North Carolina, USA). To avoid repeatedly sampling the same individual, the webbing between the outermost toes of the hind right foot was marked with a visual implant elastomer dye (http://www.nmt.us/products/vie/vie.shtml) via 30 gauge BD Ultra-Fine™ insulin syringes (see Hoffmann et al. [2008] for marking procedures). *Scaphiopus holbrookii* were then sexed, measured, weighed, and released.

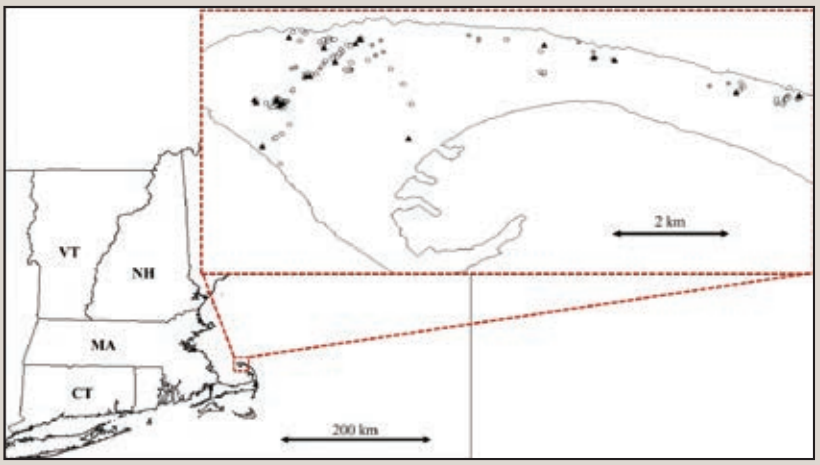

FIG. 1. Outer Cape Cod, Barnstable County Massachusetts, USA. The Provincelands of Cape Cod National Seashore (42.069975°N, 70.173116°W), outlined in red, was divided into three sampling routes based on existing trails to examine the occurrence of *Batrachochytrium dendrobatidis* (Bd) on the Eastern Spadefoot, *Scaphiopus holbrookii*. Open circles in the inset represent Bd-negative individuals, whereas gray circles and black triangles represent individuals of undetermined Bd status and Bd-positive individuals, respectively.

We placed skin swabs in 1.5 mL microcentrifuge tubes and froze the tubes until molecular analyses were conducted. We added twenty µL of proteinase K and 200 µL of digestion buffer to lyse the cells. We then incubated samples at 56°C and agitated (at 550 rpm) for 24 hours. After digestion, we isolated DNA using both BioSprint 96 and QIAcube robotic workstations (Qiagen®, Valencia, California, USA). We prepared samples for DNA purification in the BioSprint 96 with a master mix of 200µL Buffer AL, 200 µL isopropanol, and 30 µL MagAttract Suspension G (Qiagen®). We prepared samples for DNA purification in the QIAcube using the tissue extraction protocol from the QIAamp DNA Mini Kit (Qiagen®). To detect *Bd*, we prepared a PCR reaction with 12.5 µL TaqMan Mastermix (Applied Biosystems, Foster City, California, USA), 2.3 µL primer (ITS1-3Chytr and 5.8sChytr; Boyle et al. 2004), 6.25 µL MGB probe, and 2 µL of extracted DNA. We ran samples on an Applied Biosystems Prism 7700 Sequence Detection System (Applied Biosystems) at 95°C for 3 min, followed by 45 cycles of 95°C for 30-sec and 55°C for 30-sec. Presence of *Bd* was determined by comparing sample amplification rates to amplification rates of *Bd* standards derived from a transgenic *E. coli* culture (U.S. Geological Survey, Reston, Virginia, USA).

We used a Fisher's exact test to assess differences in *Bd* detection rates among sexes, sampling month and sampling region. Size differences between those that were *Bd* positive and *Bd* negative were assessed with independent sample t-tests. Normality was assessed with normal probability plots and KS tests. Equality of variance was assessed with Levene's test for equal variance (Zar 1999). For all statistical tests, $\alpha = 0.05$. Standard error is expressed after the ± symbol.

We located and marked 215 (73 males, 116 females, 26 undetermined) *S. holbrookii* in June, July and August 2011 and 2013. Significantly more were captured in July (59.5%, $\chi^2 = 92.4$, df = 2, $p < 0.001$) and none were recaptured. Only five were found in a wetland. Individuals ranged in mass from < 1 g to 34.5 g (overall $\bar{x} = 17.1$ g ± 0.43). Although the largest individual was a female (29.5 g, 2.4 g heavier than the largest male), on average, males were significantly larger ($\bar{x} = 20.0$ g ± 0.50) than females ($\bar{x} = 15.6$ g ± 0.62; t = -506, df = 187, $p < 0.001$).

Molecular analysis was successful on 190 individuals, 25 of which were *Bd*-positive (13.1%). Nineteen of the *Bd*-positive individuals (76%) were from July ($\chi^2 = 5.91$, df = 2, p = 0.05) and all *Bd*-positive *S. holbrookii* were collected on land. *Bd* was detected in a higher, but non-significant, percentage of males (20%) than females (12.5%; Fisher's exact test $p > 0.10$) and there were no significant differences in mass between individuals testing *Bd*-positive compared to those which were *Bd*-negative (t = 0.24, df = 187, $p > 0.10$), even when accounting for sex (male t = 0.61, df = 64, $p > 0.10$ [males]; = -0.04, df = 97, $p > 0.10$ [females]). Most individuals that were *Bd*-positive were obtained from the westernmost sampling area; however the central sampling area contained proportionately, and significantly, more *Bd*-positive individuals ($\chi^2 = 13.5$, df = 2, $p < 0.001$, Fig. 1).

To the best of our knowledge, this study is the first to identify the presence of *Bd* in live *S. holbrookii*, thus contributing to our understanding of *Bd* distributions and its prevalence across ecological guilds. Although *Bd* was detected in 13.1% of *S. holbrooki* sampled, we did not see potentially visible clinical symptoms of chytridiomycosis infection (abnormal posture, lethargy, loss of righting reflex, abnormal sloughing, epidermal ulceration and hemorrhages; Daszak et al. 1999). We observed a female-biased sex ratio (73 males:116 females), which is consistent with sex ratio differences identified in chytridiomycosis-related population declines in *Anaxyrus boreas* (Muths et al. 2003). However, further sampling is needed to determine if our ratio is accurately descriptive of the population. Our data support the notion that *Bd* is widespread in the northeastern United States and that it may have persisted without causing catastrophic population declines. This may be in part because regional climates are unsuitable for the level of *Bd* proliferation that has been associated with widespread chytridiomycosis (Longcore et al. 2007). It has been suggested that global climate change (Pounds et al. 2006) and the presence of additional stressors (see Davidson et al. 2003) may act synergistically, thus potentially contributing to *Bd*-related amphibian declines (Longcore et al. 2007). Therefore, we recommend that *Bd* sampling be integrated into long-term amphibian monitoring programs at Cape Cod National Seashore and that heightened biosecurity (Johnson et al. 2003) be employed to reduce *Bd* transmission between sites.

Acknowledgments.—We thank Megan Tyrrell of the Cape Cod National Seashore Atlantic Learning Center for helping to facilitate this project. Spadefoot samples were collected by Kristen Dawson, Tatiana Galitzin, David Rodriguez and Nathanial Soto of Northern Virginia Community College. Scott Buchanan of Rutgers University and Mark Faherty and Laura McHenry of the Wellfleet Bay Audubon Society also provided essential field assistance. Molecular aspects of this project were supported by Nancy McInerney of the Smithsonian's Center for Conservation and Evolutionary Genetics, Larry Rockwood of the Biology Department at George Mason University, and a Patriot Green Fund Grant from the Office of Sustainability at George Mason University. Fieldwork was approved by the Commonwealth of Massachusetts Division of Fisheries and Wildlife.

Batrachochytrium dendrobatidis Infection Rates Differ over Short Distances between Natural Lakes and Artificial Ponds in Minnesota, USA

Chytrid infection in North American amphibian populations has been well documented and is known to be widespread. There is, however, insufficient information to assess the importance of spatial and temporal fluctuations in infection rates, and more research is required to identify important anthropogenic impacts on chytrid transmission and pathogenicity.

In 2011, samples collected from two dead anurans confirmed the presence of *Batrachochytrium dendrobatidis* (*Bd*) in a small network of koi ponds in Minnesota, USA (Wolff et al. 2012). Herein, we report our results of a follow up study conducted in 2012. Our findings indicate that infection rates can vary significantly among subpopulations in an area and point to biological simplification as a potential driver of an emerging disease.

In 2012, we sampled the above mentioned koi ponds, a stormwater pond, and two naturally occurring lakes for *Bd*. The lakes and ponds all lie within or adjacent to Murphy-Hanrehan Park Reserve in southeastern Minnesota, USA (Fig. 1).

Murphy-Hanrehan Park is a 970-ha regional park located approximately 30 km south of Minneapolis, Minnesota. The Park is closely associated with three small to moderately-sized lakes. It encompasses Murphy Lake, borders Hanrehan Lake on three sides, and is situated adjacent to Orchard Lake. Murphy Lake is a shallow natural lake with an approximate maximum depth of 5 m and a surface area close to 18 ha. An aeration system is used to prevent winterkills. Hanrehan Lake is a shallow natural lake with a maximum depth of 2–3 m and a surface area of approximately 27 ha. Orchard Lake is a 95-ha naturally occurring lake with a

maximum depth of approximately 10 m. Three smaller lakes and numerous naturally occurring shallow ponds (surface area < 5 ha) are also located within, or partially within, the boundaries of the Park. Ephemeral pools are common. The Park is situated in the Minnesota River watershed. A small river creates a corridor that connects the Park to extensive wildlife habitat in the nearby Minnesota River Valley. The area surrounding the Park is primarily associated with residential and agricultural developments. Murphy-Hanrehan Park is located in the transitional zone between the temperate grassland and deciduous forest biomes and is characterized by a mix of prairie wetland and mesic forest communities. It supports populations of several Minnesota amphibians including at least 7 anuran and 2 salamander species.

The stormwater holding pond sampled was created in 2007 as part of a new residential development. The pond is approximately 60-m long with an estimated surface area and maximum depth of 600 m^2 and 1.2 m, respectively. The pond has a compacted clay-rich base and holds water throughout the year.

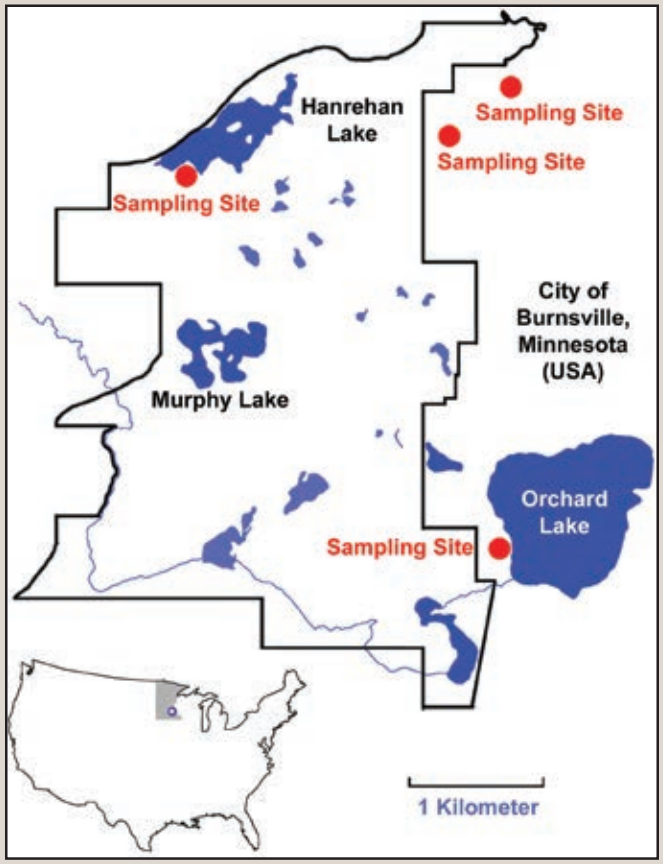

FIG. 1. Map of Murphy-Hanrehan Park Reserve, Minnesota, USA with sampling sites for *Batrachochytrium dendrobatidis* (*Bd*).

The network of small koi ponds has a combined surface area of 30 m^2 and a maximum depth of 1.05 m. The four ponds making up the network are tightly grouped. The maximum distance between ponds is less than 20 m. Water is circulated through three of the four rubber-lined ponds by a pump connected to a simple filtering system employing polyester batting as filter material. A similar system is used to filter water in the fourth pond. Water lost via evaporation is replaced via precipitation and partial refilling from a tap connected to a chlorinated city water line.

Following the mortality event observed in 2011, steps were taken to eliminate *Bd* from all of the koi ponds. Over a four-day period, beginning on 24 October, 2011, the ponds were drained. All anurans encountered in the process of draining the ponds were collected for examination and subsequently euthanized. The ponds were thoroughly dried and were not refilled prior to partial refilling by snowmelt the following spring. Filters, tubing, and pumps were disinfected by submersion in boiling water.

In 2012, frogs were captured on land and in shallow water using fresh disposable gloves, previously unused plastic garbage bags, and double-washed glass jars. Sampling took place between 12 September and 18 October. At this time of year in Minnesota, temperatures routinely drop below 5°C and frogs can be readily collected from roads, fields, pathways, and shorelines by scooping into a plastic garbage bag or jar.

We sampled 34 Green Frogs (*Lithobates clamitans*) and 7 Northern Leopard Frogs (*L. pipiens*) from natural sites at the south side of Hanrehan Lake (44.7246°N, 93.3425°W) and the west side of Orchard Lake (44.7003°N, 93.3158°W), and 30 Green Frogs and 1 Leopard Frog from the stormwater pond (44.7269°N, 93.3199°W) and koi ponds (44.7295°N, 93.3141°W). We observed no dead frogs at any of the sites sampled, or animals displaying symptoms of chytridiomycosis similar to those observed in 2011.

Captured frogs were transported to an indoor location and examined for external parasites, injuries, other peculiarities, and swabbed for *Bd*. Two and three-person teams examined and collected samples from all frogs following roles similar to those prescribed in the field sampling protocol outlined by Brem et al. (2007). Frogs were handled only by individuals wearing fresh, powder-free latex or nitrile gloves. Samples were collected with individually wrapped, plastic-handled, sterile swabs. We swabbed the underside of each rear foot 5 times, the ventral surface of each thigh 5 times, and the lower abdomen 5 times, beginning with the feet and ending with the abdomen. We immediately placed used swabs in pre-labeled vials containing 70% ethanol. Vials were stored in a dark location at room temperature prior to being shipped via FedEx second-day delivery to the Amphibian Disease Laboratory at the San Diego Zoo's Institute for Conservation Research. The samples were analyzed via real-time TaqMan PCR assay, in general accordance with the methods outlined in Boyle et al. (2004).

Because it was assumed that a substantially larger number of

TABLE 1. Results of *Batrachochytrium dendrobatidis* (*Bd*) sampling of *Lithobates clamitans* and *L. pipiens* near natural lakes and artificial ponds in the vicinity of Murphy-Hanrehan Park Reserve, Minnesota, USA.

	Natural Lakes				Artificial Ponds			
	L. clamitans		*L. pipiens*		*L. clamitans*		*L. pipiens*	
	Single	Pooled	Single	Pooled	Single	Pooled	Single	Pooled
Bd+	3	5	1	0	5	11	1	0
Bd-	13	4	0	3	3	0	0	0

specimens would be captured, some samples were pooled to manage costs. In all cases, pooled samples contained swabs from two frogs collected in the same area and belonging to the same species.

Green and Northern Leopard Frogs from the natural lakes and artificial ponds tested positive for *Bd* (Table 1). We employed the Fisher exact test to compare Green Frog infection rates between the natural and artificial sites. Separate contingency tables were used to evaluate the pooled ($p = 0.026$) and non-pooled samples ($p = 0.065$). We also calculated the mean *p*-value obtained by randomly combining the individual samples to produce an all-inclusive contingency table of pooled results ($p = 0.003$). We repeated the calculations incorporating the Northern Leopard Frog results. This increased the significance of the findings in all cases.

Despite our moderate sample sizes, we were able to detect significant differences in Green Frog infection rates between the natural and artificial sites surveyed. Our findings indicate that infection rates can vary significantly between subpopulations separated by relatively short distances. The maximum distance between collection sites was only 4.1 km.

Our results of higher frog infection rates associated with artificial ponds further suggests that *Bd*-host dynamics or *Bd* ecology may differ between artificial and natural systems. It is possible that stormwater holding ponds, decorative ponds, and similar structures serve as more optimal habitat for *Bd*. Cladocerans and other grazers, which have been shown to significantly reduce zoospore densities (Buck et al. 2011; Woodhams et al. 2011; Hamilton et al. 2012), are likely to be largely absent from many of these simplified ecosystems. Anuran predators and scavengers capable of removing infectious dead and dying frogs are also likely to be absent. As a consequence, zoospore densities may be substantially elevated. The absence of common predators may also facilitate disease transmission by permitting the development of abnormally high anuran population densities.

Artificial ponds also differ from natural ponds hydrologically. Many are lined with impervious materials and seldom dry out. There may be little or no flushing to remove *Bd* zoospores. As a result, elevated zoospore densities may be maintained for extended periods. *Bd* has been shown to be viable and infective in lake water for up to 7 weeks without an amphibian host (Johnson and Speare 2003).

Chytridiomycosis is one of a growing number of emerging plant and animal diseases. Such diseases are increasing at a disconcerting rate and pose a growing threat to human health, ecosystem health, and biodiversity (Dobson and Foufopoulos 2007; Jones et al. 2007; Meentemeyer et al. 2012). Although there is general awareness that ecological simplification and subsequent ecological release can play a role in disease emergence (Wilcox and Gubler 2005), few studies linking emergence to anthropogenic ecological simplification have been published. It cannot be determined with confidence from our observations alone that ecological simplification is a contributing factor in the emergence of chytridiomycosis. However, our results are consistent with ecological simplification enhancing *Bd* infection and transmission rates via several mechanisms. The hypothesized link between ecological simplification and disease emergence warrants further evaluation.

Acknowledgments.—This study was supported by UTC Aerospace Systems, Normandale Community College, and Three Rivers Park District. Valuable assistance was received from the San Diego Zoo's Amphibian Disease Laboratory.

Captive Husbandry and Reproduction of *Phrynosoma asio* (Squamata: Phrynosomatidae) at the Los Angeles Zoo and Botanical Gardens

Since 2003, the Los Angeles Zoo and Botanical Gardens, along with San Diego Zoo, has participated in a cooperative, ongoing study of western Mexican herpetofauna conducted by Universidad Autonoma de Nuevo Leon (UANL). One species of particular interest is the Giant Horned Lizard, *Phrynosoma asio*, which ranges along Pacific coastal forests of western Mexico from Colima south to northern Guatemala. Little is known about the natural history and breeding behavior of Giant Horned Lizards. One of the primary goals of this collaboration is to develop a baseline for successful captive maintenance and propagation of this species. As the first institution to successfully breed this species, Los Angeles Zoo staff has established several important husbandry guidelines.

Materials and methods.—In August 2008, three Giant Horned Lizards (two males, one female) were collected in the Mexican state of Colima and exported to Los Angeles Zoo. Upon arrival they were placed into a three-month quarantine. Fecal material collected during transport was preserved and the contents analyzed in an effort to better understand the natural diet of the lizards. These samples indicated *P. asio* feeds on a variety of terrestrial insects including, but not limited to, ants and termites (Recchio et al. 2009). *Phrynosoma* species generally show a range in dietary habits, but most are strongly myrmecophagous, or ant consumers (Pianka and Parker 1975; Montanucci 1989; Lemos-Espinal et al. 2004; Sherbrooke and Schwenk 2008). The habitat and dietary observations in conjunction with known husbandry protocols for other *Phrynosoma* (N. Atteberry, pers. comm.; J. Judd, pers. comm.; Montanucci 1989) were used to develop a viable captive management plan for this species.

Weekly weighing indicated that the smallest male was not gaining weight at a rate comparable to the others. While the larger pair continued to eat vigorously, the small male refused to feed and began losing weight. This lizard was assist-fed using a small index card to gently open the mouth, which initiated a feeding response. Eventually this lizard began eating voluntarily, but in order to achieve a healthy weight he was assist-fed larger, pre-killed crickets for an additional six months. This assistance with larger prey was necessary apparently due to the unique stereotyped feeding behavior resulting from highly reduced dentition and extensive pharyngeal papillae that produce a mucilaginous coating. These adaptations effectively package ants and other small prey and deliver them directly into the esophagus alive without the need to expend time and energy chewing, a requirement of other iguanids (Sherbrooke and Schwenk 2008).

Fecal tests were run on all three lizards. Each was treated for endoparasitism (unspeciated flagellates and ascarid eggs) with 50 mg/kg oral fenbendazole (Panacur®), and each continued to gain weight throughout the quarantine period. Parasitic nematodes have been found in up to 75% of some wild horned lizard populations (Sherbrooke 2003). The life cycle of *Skrjabinoptera phrynosoma* involves the horned lizard as its definitive host and the harvester ant (*Pogonmyrex* spp.) as the intermediate host,

ensuring a constant cycle of infection. This relationship can be seen in the Texas Horned Lizard (*P. cornutum*) and the Desert Horned Lizard (*P. platyrhinos*) but has not been established in *P. asio* (Sherbrooke 2003; Hilsinger et al. 2011). No other medical issues were observed. Although there is no pathology associated with this parasitism, it is possible that a significant load might adversely affect digestion (Babero and Kay 1967).

Upon release from quarantine, the lizards were placed in an opaque 378-liter Rubbermaid® plastic stock tank with approximately 25 cm of substrate consisting of 80% sand and 20% soil. The ambient temperature was 28°C ± 2°C with relative humidity of 70% ± 10%. A basking area was created utilizing a 160-watt Zoo Med PowerSun® mercury vapor bulb and a 100-watt Zoo Med Repti Halogen® bulb over large stones. These produced surface temperatures ranging from 30–37°C. A 10.0 T8 Zoo Med ReptiSun® fluorescent lamp was placed over the cooler side of the enclosure for additional UVB exposure. Clusters of both live and artificial bunch grasses were planted throughout the enclosure. This provided nesting and hiding places as well as variation in topography. A large shallow water dish was provided for soaking and drinking (Fig. 1).

Many *Phrynosoma* are seasonally crepuscular—diurnal in spring and fall, and bimodal in the summer (Pianka and Parker 1975). To elicit the best feeding response, food items were offered at least twice daily during periods of highest activity. The lizards were offered harvester ants (*Pogonomyrmex* sp.) daily from a specialized feeding device buried in the substrate so as to mimic an anthill (Fig. 2). This was constructed by staff using a 12-cm diameter by 12-cm tall cylindrical plastic storage container. A 5-cm hole was drilled in the lid and a 20-cm long wooden dowel rod was inserted and secured to the bottom of the container, protruding through the lid. The ants were able to climb up the rod but not escape. *Phrynosoma asio* are less sensitive to the stings of *Pogonomyrmex* venom due to a blood plasma factor that aids in detoxifying the venom. However, the venom can become fatal if the lizard is stung too many times (Sherbrooke 2003; Sherbrooke and Schwenk 2008). Therefore, we monitored and removed any uneaten ants daily. If suitable and sustainable local sources for harvester ants are not available, they can be obtained from commercial suppliers, in this case, Life Studies (www.lifestudies.com). Other species of ants such as *Iridomyrmex pruinosus* can be fatal to horned lizards due to a defensive chemical (methyl-n-amyl ketone) that is aerosolized when the ant is disturbed (Blum et al. 1963; Montanucci 1989).

A varied diet is important not only from a nutritional standpoint, but also for enrichment. One study concluded that termites make up the most numerically important single prey item based on stomach content analysis (Lemos-Espinal et al. 2004). These results are consistent with *P. asio* having a more generalized diet than other *Phrynosoma*. Due to insufficient and seasonal availability of termites, crickets (*Acheta domestica*) became the staple daily food item, with wax worms (*Galleria mellonella*) offered several times weekly. Keepers also collected insects from zoo grounds in an effort to mimic natural dietary variation. Prey items offered included carpenter ants (*Camponotus* sp.), termites (Isoptera), red-legged earwigs (*Euborellia annulipes*), European earwigs (*Forficula auricularia*), and the occasional juvenile multicolored centipede (*Scolopendra polymorpha*). One feeding per day was lightly dusted with ReptiVite™ vitamin and calcium powders with D3. Feces were frequently inspected to ensure the lizards were both ingesting ants and properly digesting food items. *Phrynosoma* have a very large stomach in comparison to other iguanids as a function of their dietary specialization on ants, requiring a large volume to meet nutritional needs (Montanucci 1989; Pianka and Hodges 1998; Sherbrooke 2003; Sherbrooke and Schwenk 2008).

Observations and results.—Phrynosoma asio were often seen licking each other, head bobbing, and basking on top of or near each other. No aggressive behaviors have been observed in mixed gender and bachelor groups. These lizards appeared to thrive in a communal environment, potentially due to the need to live in close proximity to anthills and termite mounds. While this species is capable of ocular-sinus blood squirting (Hodges 2004), this behavior has never been observed in this group, which has become accustomed to daily handling.

Every effort has been made to mimic conditions of photoperiod, temperature, humidity, and diet found in *P. asio*'s natural habitat. In the tropical deciduous forests of southwestern Mexico, the dry season lasts typically from November through April and the arrival of rain stimulates breeding. Approximately one year after acquisition, the lizards had reached a sexually mature size: minimum 91 mm snout-to-vent length and weight greater than 70 g (J. Judd, pers. comm.; Pianka and Parker 1975), and were cycled through a winter brumation. This process first entailed lowering basking temperatures and reducing the frequency of misting. Conditions were gradually changed from 28°C with 60–70% humidity to conditions ranging from 24°C during the day to 18°C at night with 40–50% humidity, mimicking natural winter conditions. Hot spots were maintained at approximately 29°C during the day and 26°C at night. A hibernaculum of 8 cm of clean, dry leaves was provided.

During brumation, the *P. asio* were semi-active, utilizing hot spots intermittently. Primarily, the lizards buried themselves under the leaf litter layer on the cool end of the enclosure. When the lizards showed activity, harvester ants were offered, utilizing the feeding device. However, feeding was observed on only a few occasions. The lizards were misted only when active to induce drinking. Due to a significantly reduced metabolic rate during brumation, the lizards may drink, but rarely eat (Mayhew 1965). Water is still necessary and was made available at all times although the substrate was allowed to dry out. The lizards' weights and body condition were closely monitored. During the four-month brumation period, which ended in April 2010, the lizards lost an average of 10.7% of their body weight.

FIG. 4. Male *Phrynosoma asio* showing enlarged post-anal scales (left) Female with no scale enlargement (right).

This was quickly regained and further growth was observed once normal activity and feeding resumed. In June, the summer light cycle was increased from 8 to 12 h.

In wild populations, breeding usually occurs in May and June (Davis and Dixon 1961) or June and July in captivity (Baur 1979). In our group, breeding took place on 20 July 2010. The female displayed to the males by holding her tail up vertically and waving it side to side; head bobbing and arm waving were also seen. Males experienced decreased appetite during the breeding season. The smaller male initiated copulation by chasing the female and licking at the base of her tail. The male then mounted the female, grasping the nuchal folds around her neck with his mouth and then swung his tail under hers to align the cloacae. This entire process took place in a matter of minutes.

Prior to this observed copulation, the female had increased her fat reserves. After breeding she exhibited a decrease in appetite, and her abdomen became distended. She was restless during gestation, which can range from 30–60 days. As she grew closer to oviposition, her abdomen became visibly lumpy. On 18 August, the female laid 20 eggs in a nest about 7 cm deep directly underneath the heat lamp, which was turned off during the laying process to decrease the potential for egg desiccation. The following year, the same female laid 19 eggs. These numbers are consistent with the previously recorded average clutch size for *P. asio* of 16.9 with a standard deviation of 4.9 (Pianka and Parker 1975; Pianka and Hodges 1998).

During the 2010 egg deposition, the female was left in privacy; in 2011 she was monitored closely and video-recorded throughout the process by staff in attendance. The female began excavating a nest in the same location as the previous year, using her forelegs to dig and her hind limbs to push the substrate further away. She was observed rolling individual eggs under her tail so as to coat each with substrate. This may serve both to camouflage the white eggs and to prevent them from sticking together (Sherbrooke 2003). When oviposition was completed, the female covered the eggs with soil. She would scoop a small amount of soil over the nest, then with a jackhammer-like motion pounce rapidly with her forelegs while her hind end remained stationary. The motion was so quick that it appeared as a blur on video recordings. She repeated the scooping and tamping process for several hours. When finished, she resumed basking and consumed a small meal. Her feedings were increased and supplemented heavily with powdered vitamins and calcium. Within 30 days she had returned to her pre-gravid weight. The weight loss observed was consistent with other species in the genus, where the Relative Clutch Mass (RCM) constitutes 13–35% of the female's weight (Pianka and Hodges 1998). All lizards quickly returned to their pre-breeding body condition and activity levels.

The eggs laid in 2010 were excavated and placed on fine vermiculite substrate inside a 3-liter, clear, snap-top plastic container with series of six 4-mm holes punched around the rim of the container. Due to a lack of available baseline data, an initial vermiculite-to-water ratio of 4:1 by weight was chosen to avoid oversaturation with water. This container was placed in an Avey RCAB200 Reptile Incubator™ at 31°C and 92% humidity. After a few days, the eggs began to desiccate. Under these conditions 11 of the 20 eggs withered, appeared nonviable and were discarded. The incubation temperature was reduced to 26.5°C and ambient humidity decreased to 70% in order to compensate for increased substrate moisture. The vermiculite-to-water ratio was doubled to 2:1 by weight, a small water bowl was added to the container, and the lid was gently misted to maintain light condensation. Specific humidity levels were not determined. Under these conditions the remaining nine eggs began swelling and appeared to thrive.

The first egg hatched after 100 days; the last egg after 106 days. The neonates took several days to fully emerge and frequently appeared static and lifeless. As with other reptile species, this is a period of transition during which the neonates absorb their yolk into their abdomen and switch from embryonic breathing to lung breathing. Therefore it is important to avoid interfering with the hatching process (Fig. 3). All nine neonates appeared normal and weighed between 1.8–2.5 g with an average weight of 2.2 g. They remained in the incubator for 24 h in order to fully absorb the yolk sac and gain strength. Preliminary sexing once the male hatchlings' enlarged post-anal scales were large enough to examine with a hand lens (approximately 5 g) suggested that the clutch consisted of eight males and one female (Fig. 4).

The 2011 clutch was incubated in a different manner. Of the 19 eggs, four appeared undersized. As with the 2010 clutch, the eggs were not weighed; however, based on the female's post-oviposition weight loss, the assumed average egg weight was 1.7 g. Two incubation containers were set up with a vermiculite-to-water ratio of 2:1 and a small water dish for added humidity. Six of the eggs were placed in a Percival I-36NL™ incubator set to 28°C. Three of these eggs remained undersized (less than one gram each), and began to shrivel and mold. They were therefore discarded. The remaining 13 eggs were incubated in an Avey RCAB200 Reptile Incubator™ at 26.5°C; after one week, one

undersized egg began to shrivel and mold. It, too, was discarded. The three eggs in the 28°C incubator began hatching between 85–92 days. Individuals ranged in weight from 1.4–1.6 g, with the average weight of 1.5 g. The remaining 12 eggs in the 26.5°C incubator hatched between 107–112 days. These individuals ranged in weight from 1.7–2.1 g, with an average weight of 1.9 g. The clutch incubated at a lower temperature took an additional 16–21 days to hatch and the hatchlings were, on average, 23% larger by weight at hatching than the higher temperature clutch. Once the hatchlings reached approximately 5 g in weight, preliminary sexing revealed that the three incubated at 28°C were females. The 12 hatchlings from the 26.5°C incubator consisted of four males and eight females. Because the smaller male was observed breeding the female, and because we have noted that distinctive skin patterns appear to be hereditary, we conclude that the smaller male sired the 2010 clutch and the larger male (which was the only observed copulation the following year) sired the 2011 clutch.

The 2010 neonates were housed in groups of four and five individuals, divided between two 38-liter glass aquariums. They were placed on moist paper towels with Petri® dishes for water. A large smooth rock was provided for basking and sleeping. A 50-watt Zoo Med Repti Halogen® bulb was placed over the basking rock to achieve 30–37°C. A 10.0 T8 Zoo Med ReptiSun® fluorescent lamp was placed evenly over both tanks to provide additional light and UVB exposure. The neonates were housed in the same room as the adults. No aggression was observed between the neonates and they often basked and slept on top of or next to each other. They were often observed licking each other and their surroundings. When the lizards were housed separately, their activity levels decreased. The neonates from the second clutch were treated in an identical manner as the first hatchings.

The neonates were offered as wide a variety of insects as possible, two to four times daily to ensure equal access for all individuals. The neonates had access to termites throughout the day when available. Pinhead crickets were offered twice daily in quantities that the lizards could consume within 10–15 minutes. The lizards demonstrated definite food preferences and specific techniques were developed to increase consumption of less desirable items to ensure varied and complete nutrition. Although the lizards showed a strong aversion to harvester ants (which could bite and sting them), the formic acid they contain may be an important component of *P. asio*'s diet. Formic acid is known to be an important gut flora component because it lowers pH levels, initiates protein synthesis, and aids in water extraction from consumed ants.

Feeding harvester ants to the lizards was best accomplished as the first feeding of the day and by placing a few in a container with vitamin powder to disguise them, then chilling them for 30 minutes to slow their movement. The smallest ants were then fed to the lizards one or two at a time until the ants become too active. It was not uncommon for the lizards to eat a single ant every few days. If more than a few ants were eaten at a time the lizards snapped their mouths open and shut repeatedly as if they were experiencing irritation inside of their mouths. Neonates appeared to consume ants more readily than their wild-caught parents.

Termites of any variety were the most preferred food items. The termites with their frass and other debris with which they were collected were presented to the lizards on a small dish or on a piece of wood. They often watched the debris or wood for extended periods of time waiting for the termites to emerge, though they did not actively dig to uncover them. If diligent collection efforts fail, termites are available from commercial biological supply companies. Pinhead and crickets up to 5 mm comprised the majority of the captive *P. asio* diet. Black carpenter ants were highly favored compared with harvester ants. Juvenile earwigs were also occasionally eaten. Small wax worms were fed to neonates, though they often tasted but did not consume them.

Neonates were rarely seen drinking from dishes, so, as with the adults, they were misted on their heads with a hand sprayer three to six times daily (and always after feedings) to ensure proper hydration. It was important to avoid oversaturation of their substrate to eliminate the potential for contact sores. They were also soaked twice weekly in shallow water (no more than 5 mm deep) during routine enclosure cleaning to prevent shed skin from remaining on their digits. Under these conditions the neonates thrived and developed adult behaviors as they grew and matured. These lizards require a high level of attention and care in a captive environment.

The purpose of this paper is to establish baseline criteria for the captive management and propagation of *P. asio*. Research continues to improve the husbandry for this charismatic lizard. Captive studies allow for unique insights that would be difficult to obtain under wild and often hostile conditions. The Los Angeles Zoo aims to improve on previous hatching success and to further insure healthy captive populations. Through continued efforts and shared knowledge, Giant Horned Lizards may one day thrive in other facilities, allowing for broader exposure, a greater knowledge base, and a healthy assurance population of this unique species.

Acknowledgments.—We thank David Lazcano, Brett Baldwin, Nicole Atteberry, Carlos Martinez, and most importantly, we would like to extend our gratitude to the many people of Mexico who assisted us in the field and allowed us access to their "Chamaleónes," SEMARNAT, and the Mexican government who granted us access to their country, its wonderful herpetofauna, and ecological diversity. All research and collecting was done under the authority of SEMARNAT scientific research permit oficio num.SGPA/DGVS/03804 issued to IR.

HERPETOCULTURE NOTES

TESTUDINES — TURTLES

***SIEBENROCKIELLA LEYTENSIS* (Philippine Forest Turtle). ARTIFICIAL INCUBATION AND HATCHLING SIZE.** *Siebenrockiella leytensis* is the largest and heaviest Philippine geoemydid turtle attaining > 300 mm in median caparace length and weighing > 3.5 kg. As currently understood, it is the only endemic Philippine turtle and its natural distribution is on Palawan and Dumaran Island, Philippines (Diesmos et al 2012. *In* Rhodin et al [eds.], Conservation Biology of Freshwater Turtles and Tortoises. Chel. Res. Monogr. No. 5:066.1–9).

Since 2008, a few commercial turtle traders in the United States and Europe have offered for sale apparently captive bred *S. leytensis* on the Internet with prices ranging from US $2500–4500 per specimen (pers. obs.). In the Philippines, there were also anecdotal claims made by turtle enthusiasts and private zoological parks of successful hatching of *S. leytensis* eggs from wild-caught specimens and/or captive breeding. One private zoological park in the Philippines claimed to have produced > 100 *S. leytensis* hatchlings in 2010 (S. Schoppe, pers. comm.). Interestingly, no credible evidence is forthcoming such as photographs of hatchling emerging from egg to authenticate purported captive hatching or breeding successes. Herein, I report on the artificial incubation and a full-termed hatchling of *S. leytensis*.

On 10 January 2013, a *Siebenrockiella leytensis* egg was laid by a wild-caught female (SCL = 199 mm) and donated by a private individual to me on the same day for artificial incubation. The female *S. leytensis* was in captivity with no contact with conspecifics for at least 45 days prior to laying the egg. The egg measured 50.35 mm in length × 28.75 mm in width and weighed 26.8 g. The egg size and mass were within the range previously documented for captive *S. leytensis*, which ranged from 41.0–57.8 mm in length × 19.7–29.4 mm in width and weighed 18–30 g (Diesmos et al 2012, *op. cit.*). No data are available on *S. leytensis* eggs from the wild. The egg was immediately placed in a plastic container with a ~5-cm thick layer of moistened vermiculite as incubation medium. Temperature during the entire incubation period ranged from 27°C–31.5°C. Recorded daily variation of incubation temperature was 0°C–3°C.

On 27 April 2013 (day 107), water beads on top of and a slight crack on one end of the egg were observed. Two days later (day 109), a lateral crack was observed, but no attempt was made to assist the hatchling. The following day, the hatchling failed to emerge on its own and upon opening the egg on the same day, a deceased hatchling was observed. The hatchling had the following measurements: 43.2 mm carapace length × 27.1 carapace width × 21.4 carapace height, and mass of 15.3 g. Hatchlings observed in the wild were 41–44.7 mm in median caparace length and weighed 12–15 g (Schoppe 2009. *Siebenrockiella leytensis* over time—are populations stable? Katala Foundation, Palawan, Philippines. 13 pp.). In comparison, the mean size and mass of eggs laid in captivity by the congeneric *S. crassicollis* were 52.1 mm in length × 28.0 mm in width and 27.2 g, respectively (Honegger 1986. Salamandra 22:1–10). *Siebenrockiella crassicollis* eggs incubated at 29°C–30°C hatched after 68–84 days; hatchlings were 43–46 mm carapace length and weighed 14–15 g (Honegger, *op. cit.*). To my knowledge, this is the first recorded artificial incubation of a *S. leytensis* egg to full term.

SQUAMATA — LACERTILIA

***HELODERMA CHARLESBOGERTI* (Guatemalan Beaded Lizard). CANNIBALISM.** *Heloderma charlesbogerti* is a critically endangered species of venomous lizard that occurs only within the Motagua Valley of Guatemala (Beck 2005. Biology of Gila Monsters and Beaded Lizards. University of California Press, Berkeley, California. 224 pp.). Conservation initiatives are underway *in situ* and *ex situ* within Guatemala. In addition, Zoo Atlanta maintains an *ex situ* colony of more than 20 *H. charlesbogerti* of various age classes as part of a conservation breeding program.

On 25 December 2013 at ~0730 h we observed an individually housed female *H. charlesbogerti* shortly following oviposition. This female began laying eggs on 18 December 2013. Because the egg appeared freshly oviposited—still wet—and was positioned adjacent to the female's cloaca, the decision was made to leave the egg in place to prevent disturbance should she continue to lay eggs. At ~ 0850 h she was checked again. The egg was missing and she had changed position within the nest chamber. A thorough search of the entire enclosure was conducted and no eggs were recovered, leaving us with the obvious conclusion that she had eaten the egg. She deposited two more eggs on 26 and 27 December 2013 and was deemed to have completed ovipositing.

At ~0700 h on 2 January 2014 during routine checks, RLH observed two partially digested eggs in her enclosure, confirming that this particular female had consumed not only one, but two of her own eggs (Fig. 1). It is not clear whether these eggs were regurgitated or passed completely through the gastrointestinal tract, however, as no obvious fecal matter was associated with them.

In addition to the observation above, another female in the collection that was also individually housed and confirmed to be gravid with at least six eggs via radiography and ultrasound imaging was observed to deposit only two eggs while the remaining eggs were never found. These eggs were not observed on subsequent radiographs. The assumption was made that she had consumed her eggs as well, but we were unable to directly verify this.

Various studies have shown that reptile eggs are relatively common items in the diet of *H. charlesbogerti* specifically (Beck 2005, *op. cit.*). As there are few data on clutch size and oviposition habits of wild *H. charlesbogerti,* it is unknown if wild females predate their own eggs and if these observations of individuals cannibalizing their own eggs are artifacts of captivity.

SQUAMATA — SNAKES

***BOAEDON* (*LAMPROPHIS*) *FULIGINOSUS* (African House Snake). LONGEVITY.** *Boaedon fuliginosus* are small sub-Saharan lamprophiids with a maximum reported longevity of 7–9 years (Snider and Bowler 1992. Longevity of Reptiles and Amphibians in North American Collections. Society for the Study of Amphibians and Reptiles, Herpetological Circular No. 21; Carey and Judge 2002. Life Spans of Mammals, Birds, Amphibians, Reptiles, and Fish. Odense Univ. Press, Odense, Denmark. 241 pp.; Slavens and Slavens 1999. Reptiles and Amphibians in Captivity—Breeding, Longevity, and Inventory; http://www.pondturtle.com/lsnakec.html). This species reaches sexual maturity remarkably quickly, often in less than one year, and has been used as an exemplar of a short-lived (*r*-selected) species with high fecundity (e.g., Robert et al. 2007. Aging Cell 6:395–404; Bronikowski 2008. Age 30:169–176). We report a captive male *B. fuliginosus* that lived for at least 18 years 5 months.

One of us (DL) purchased the snake as a juvenile from Glades Herp in Fort Myers, Florida, receiving it on 19 October 1994. Most *B. fuliginosus* imported by Glades Herp at this time were of South African origin (R. Roy, pers. comm.). Although there is some taxonomic confusion within this group, this specimen agreed in all scalation characters with the definition given for *Boaedon* by Kelly et al. (2011. Mol. Phylogenet. Evol. 58:415–426). The snake was given to HMH by DL in fall of 1998, by which time it had grown to adult size, and since passed from HMH to AMD and then to SD. Although size records were not kept, the snake appeared to grow very little between 1998 and 2013, when it died on 24 March, apparently of natural causes. It had eaten less than one week before death. Although our individual never reproduced, trade-offs between lifespan and reproduction are expected to be minimal in male animals (e.g., Maklakov et al. 2008. Curr. Biol. 18:1062–1066). At death, it measured 61.5 cm in snout–vent length, 3.5 cm shy of the record.

GEOGRAPHIC DISTRIBUTION

GYMNOPHIONA — CAECILIANS

***CAECILIA SUBNIGRICANS* (Magdalena Valley Caecilian).** COLOMBIA: DEPARTAMENTO DE NORTE DE SANTANDER: El Cejal creek, about 32.3 km NW of municipality of Toledo (7.16547°N, 72.22698°W; datum WGS 84), 800 m elev. 12 March 2011. A. Acevedo, R. Franco, and K. Silva. Museo de Ciencias Naturales, University of Pamplona, Pamplona, Colombia (MCNUP-170). Verified by J. D. Lynch. Species known from Venezuela (east of the Maracaibo Lake basin, Barinas and Táchira states; Barrio Amorós 2004. Rev. Ecol. Lat. Am. 9[3]:1–48), and from Colombia (Valle del Cauca, Nariño, Risaralda, Tolima, Bolivar, Magdalena, Cordoba, and Sucre states; Lynch 1999. Rev. Acad. Colomb. Cienc. 23:317–337; Acosta-Galvis 2000. Biota Colombiana 1[3]:289–319). First department record, and first from eastern flank of the Eastern Cordillera of Colombia, border with Venezuela; extends the known distribution approximately 350 km SE from the Colombian Caribbean region in Sucre state and approximately 450 km NE from the Colombian Central Cordillera in Tolima state. For Venezuela, this new record is about 105 km to the SW of the nearest locality in Tachira State (Uribante river). The new record partially fills the distributional gap between Colombia and Venezuela.

ALDEMAR A. ACEVEDO (e-mail: bioaldemar@gmail.com), **ROSMERY FRANCO,** and **KAREN SILVA**, Km 1 vía Bucaramanga, Universidad de Pamplona, Edificio Camilo Daza, Laboratorio de Ecología y Biogeografía CD-209, Pamplona, Norte de Santander, Colombia.

CAUDATA — SALAMANDERS

***AMBYSTOMA TIGRINUM* (Eastern Tiger Salamander).** USA: OHIO: Seneca Co.: Adult male found AOR on the E side of County Rd. 57 (County Rd. 57 is along the boundary between Seneca Co. and Hancock Co.), 10.6 km NNW of Carey (41.04354°N, 83.42046°W; WGS 84). 07 April 2014. S. Graham and C. Kelehear. Verified by David Laurencio. AUM AHAP-D 789 (digital photo voucher). New county record (Davis et al. 2013. Amphibians of Ohio. Ohio Biol. Survey Bul. 17:1–899).

SEAN P. GRAHAM, Department of Biology, University of Findlay, 1000 N. Main St., Findlay, Ohio 45840, USA (e-mail: graham@findlay.edu); **CRYSTAL KELEHEAR**, School of Biological Sciences, University of Sydney, Camperdown, New South Wales, Australia (e-mail: crystal.kelehear@hotmail.com).

***CRYPTOBRANCHUS ALLEGANIENSIS ALLEGANIENSIS* (Eastern Hellbender).** USA: TENNESSEE: Jackson Co.: Cordell Hull Reservoir at Cumberland River Mile 342 (36.329025°N, 85.766187°W; NAD 1983). 17 May 2014. John M. McCord, Wesley J. Fox. Verified by A. Floyd Scott. Austin Peay State University Museum of Zoology (APSU 19495, 19496, color photos). New county record (Redmond and Scott 1996. Atlas of Amphibians in Tennessee. Misc. Publ. No. 12, The Center for Excellence in Field Biology, Austin Peay State University, Clarksville, Tennessee. 94 pp. Internet version [http://apbrwww5.apsu.edu/amatlas/title.htm] accessed 22 May 2014; latest update 19 May 2014). Two adults measuring 38 cm and 43 cm, respectively, were incidentally captured on a trotline anchored to the riverbed and baited with chicken breast, chicken liver, and live minnows for catfish. Capture site was a deep (12–17 m) section of the main river channel along a steep rock bluff with mud substrate. Specimens were measured, photographed, and immediately released at the capture site.

JOHN M. McCORD, Tennessee Wildlife Resources Agency, Cookeville, Tennessee 38501, USA; e-mail: michael.mccord@tn.usda.gov.

***EURYCEA GUTTOLINEATA* (Three-lined Salamander).** USA: GEORGIA: Floyd Co.: Unnamed spring adjacent to Morrison Campground (34.2758°N, 93.4175°W; WGS 84). 7 June 2000. N. Burkhead, R. Lewis, and C. Skelton. Verified by John Jensen. Georgia Museum of Natural History (GMNH 50654–50656). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp). Three adults were electroshocked out of thick beds of watercress during a fish survey. In this part of the state, the ranges of *E. guttolineata* and *E. longicauda* interdigitate and are not well-established, increasing the importance of this documented occurrence.

TODD PIERSON, Environmental Health Science, University of Georgia, Athens, Georgia 30602, USA (e-mail: twpierso@uga.edu); **ADAM G. CLAUSE**, Warnell School of Forestry and Natural Resources, University of Georgia, Athens, Georgia 30602, USA (e-mail: adamclause@gmail.com); **TROY J. ANURA — FROGS

***CRAUGASTOR AUGUSTI* (Barking Frog)**. MÉXICO: AGUASCALIENTES: Municipality of El Llano: Cerro Juan Grande (21.931731°N, 101.918010°W; WGS84), 2265 m elev. 18 May 2013. Rubén A. Carbajal Márquez, Gustavo E. Quintero-Díaz. Verified by Bradford Hollingsworth. SDSNH HerpPC 05220. First municipality record, which bridges about a 71-km gap between northwestern populations in the Sierra Fría, Aguascalientes and southeastern population 76 airline km N of Lagos de Moreno, Jalisco (Vázquez-Díaz and Quintero-Díaz 2005. Anfibios y Reptiles de Aguascalientes, 2nd ed. CONABIO y CIEMA, México. 318 pp.; HerpNET 2013). The frog was found within a rock crevice in a ravine covered by xerophytic vegetation and oak forest.

RUBÉN ALONSO CARBAJAL-MÁRQUEZ, Centro de Investigaciones Biológicas del Noroeste, Instituto Politécnico Nacional No.195 Col. Playa Palo de Santa Rita Sur, C.P. 23096, La Paz, Baja California Sur, México (e-mail: redman031@hotmail.com); **GUSTAVO E. QUINTERO-DÍAZ** (e-mail: gequintmxags@hotmail.com), **CHRISTIAN MARTIN GARCÍA-BALDERAS**, **ANA GISEL PÉREZ-DELGADILLO,** and **RARAMURI REYES-ARDIT**, Universidad Autónoma de Aguascalientes, Centro de Ciencias Básicas, Departamento de Biología, Avenida Universidad No. 940, Aguascalientes, Aguascalientes 20131, México.

***CRAUGASTOR AUGUSTI* (Barking Frog)**. MÉXICO: JALISCO: Municipality of Ojuelos de Jalisco: ca. 1.8 km (airline) W from Las Negritas, Asientos, Aguascalientes (21.986518°N, 101.896406°W; WGS84), 2173 m elev. 15 June 2013. Rubén A. Carbajal Márquez, Christian M. García Balderas, Ana Gisel Perez Delgadillo. Verified by Bradford Hollingsworth. SDSNH HerpPC 05221. First municipality record, extending the range ca. 6.5 airline km NNE from the closest locality at Cerro Juan Grande, El Llano, Aguascalientes, México (SDSNH HerpPC 05220; Carbajal-Márquez et al. 2014. Herpetol. Rev. 45[3]:457). The frog was found within a rock crevice on a hill slope covered with xerophytic vegetation.

RUBÉN ALONSO CARBAJAL-MÁRQUEZ, Centro de Investigaciones Biológicas del Noroeste, Instituto Politécnico Nacional No.195, Col. Playa Palo de Santa Rita Sur, C.P. 23096, La Paz, Baja California Sur, México (e-mail: redman031@hotmail.com); **GUSTAVO E. QUINTERO-DÍAZ** (e-mail: gequintmxags@hotmail.com), **CHRISTIAN MARTIN GARCÍA-BALDERAS**, **ANA GISEL PÉREZ-DELGADILLO,** and **RARAMURI REYES-ARDIT,** Universidad Autónoma de Aguascalientes, Centro de Ciencias Básicas, Departamento de Biología, Avenida Universidad No. 940, Aguascalientes, Aguascalientes 20131, México.

***CRAUGASTOR OCCIDENTALIS* (Taylor's Barking Frog)**. MÉXICO: AGUASCALIENTES: Municipality of Calvillo: Sierra El Laurel, 4.3 km SE of Jaltiche de Arriba (21.738502°N, 102.772345°W; WGS84), 1913 m elev. 17 May 2011. Gustavo E. Quintero Díaz and Carolina Chávez Floriano. Verified by Luis Canseco Márquez. UAA-CV 0356. First record for Aguascalientes, extending the distributional range of the species ca. 57.2 airline km NE from the closest known locality in the Sierra Morones, 7.74 km WSW of Juchipila, Zacatecas (Arenas-Monroy et al. 2012. Herpetol. Rev. 43:298). The frog was found on the banks of a stream in riparian forest surrounded by oak forest. Its occurrence in Aguascalientes was expected based on habitat similarities with the nearest previously reported sites, all of which are probably influenced by the presence of Juchipila Canyon, a dispersal corridor whose watershed system has allowed tropical biota to disperse upward into highland areas (Baker et al. 1967. Amer. Midl. Nat. 77:223–226).

Playa Palo de Santa Rita, C.P. 23090, La Paz, Baja California Sur, México.

***ELEUTHERODACTYLUS CYSTIGNATHOIDES* (Rio Grande Chirping Frog)**. USA: TEXAS: Comal Co.: intersection of Ashmore St. and Guada Coma Dr. in New Braunfels (29.70002°N, 98.11390°W; WGS84). 10 October 2013. J. Eric Lee. Verified by Travis LaDuc. TNHC 89687. New county record (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps, Texas A&M University Press, College Station, Texas. 447 pp.). Several frogs were heard chorusing, with a single adult being captured by hand. Frogs were located in residential brush piles and gardens ~ 90–100 m from the Guadalupe River.

J. ERIC LEE, Balcones Wildlife Management, New Braunfels, Texas 78130, USA; e-mail: ericlee@balconeswildlife.com.

***ELEUTHERODACTYLUS CYSTIGNATHOIDES* (Rio Grande Chirping Frog)**. USA: TEXAS: Guadalupe Co.: Sidenberger Property, 3.01 km SSE of jct Hwy 90 and Eden Rd. (29.540868°N, 97.867830°W; WGS 84). 30 July 2013. Drew T. Harvey. Verified by Travis J. LaDuc, Texas Natural History Collections (TNHC 85870). A single specimen was observed under lights and captured by hand, representing the first recorded occurrence of this species in Guadalupe Co. (Dixon 2013. Amphibians and Reptiles of Texas: with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. Texas A&M University Press, College Station, Texas. 447 pp.).

Multiple individuals were also heard calling along the moist sloping ridge into a pecan bottom running along the Guadalupe River. We suspect this is a range expansion of the Rio Grande Chirping Frog given there were no south Texas plants, exotic to this region, in the area where the specimen was found.

DREW T. HARVEY (e-mail: dh1303@txstate.edu), **DOMINIC L. DESANTIS**, **ROMEY L. SWANSON**, and **THOMAS R. SIMPSON**, Department of Biology, Texas State University, San Marcos, Texas 78666, USA.

***ELEUTHERODACTYLUS PLANIROSTRIS* (Greenhouse Frog)**. USA: FLORIDA: Gilchrist Co.: Trenton, 250 m NNE from the intersection of SE 25th Ave and SE 100th St (29.594233°N, 82.763778°W; WGS 84). 02 February 2010. Cody G. Godwin. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 157499). New county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final Report, Florida Fish and Wildlife Conservation Commission, Tallahassee, Florida. 524 pp.) Found in a hole in a live oak (*Quercus virginiana*) ca. 3.6 m above ground.

This small anuran (typically 16–32 mm SVL) is native to Cuba. It is one of the earliest recorded non-native species in Florida and is a common resident in the state (Conant and Collins 1998. A Field Guide to Reptiles & Amphibians, Eastern and Central North America. 3rd ed., expanded. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.). Eggs are typically laid in moist leaf litter and soils. An aquatic larval phase is skipped and the egg develops directly into a juvenile frog. This allows them to be stowaways in ornamental plants.

CODY D. GODWIN, University of Florida, Gainesville, Florida 32606, USA; e-mail: codydg1dwin@ufl.edu.

***ELEUTHERODACTYLUS PLANIROSTRIS* (Greenhouse Frog)**. USA: MISSISSIPPI: Jackson Co.: University of Southern Mississippi's Gulf Coast Research Laboratory (GCRL), 759 E Beach Drive, Ocean Springs (30.39428°N, 88.79693°W; WGS 84). 14 May 2014. Jennifer Y. Lamb and Matthew W. H. Chatfield. Verified by Robert L. Jones. Mississippi Museum of Natural Science (MMNS 19383, 23.3 mm SVL; MMNS 19384, 18.0 mm). New county record (Meshaka Jr. 2005. In M. Lannoo [ed.], Amphibian Declines: The Conservation Status of United States Species, pp. 499–500. Univ. California Press, Berkeley; R. L. Jones, pers. comm.).

Closest known locality is ca. 17 miles W in Gulfport, Harrison Co., Mississippi (MMNS 9274–9276). The USGS Nonindigenous Aquatic Species Database has an unconfirmed record for *E. planirostris* from Jackson Co., but the locality is unspecified (Somma 2014. *Eleutherodactylus planirostris*. USGS Nonindigenous Aquatic Species Database, Gainesville, Florida. http://nas.er.usgs.gov/queries/FactSheet.aspx?speciesID=61, Revision date: 1 Nov. 2011).

Two individuals were found and collected at GCRL from beneath an assortment of cover objects at night after heavy rains. The larger of the vouchers is a gravid female, but we did not hear calling males on the premises. These specimens were collected under Mississippi Department of Wildlife Fisheries and Parks Permit 0422131.

TESTUDINES — TURTLES

***APALONE MUTICA* (Smooth Softshell)**. USA: MISSOURI: Perry Co.: Brazeau Township, near bank of Mississippi River, 10 m E of BNSF railroad and 0.5 km NW of Cottonwood Island (37.6117°N, 89.5169°W; WGS84). 2 July 2013. Andrew P. Braun and John West. Verified by Dustin S. Siegel. University of Missouri-Columbia (UMC 2392P). New county record (Edmond and Daniel 2014 [latest update: 18 February 2014]. Missouri Herpetological Atlas Project. Available at http://atlas.moherp.org/; accessed 4 June 2014). Male specimen, captured in fyke net.

ANDREW P. BRAUN (e-mail: Andrew.Braun@mdc.mo.gov), and **JOHN WEST**, Big Rivers & Wetlands Field Station, Missouri Department of Conservation, Jackson, Missouri 63755, USA.

***APALONE SPINIFERA* (Spiny Softshell)**. USA: TENNESSEE: Lewis Co.: Dan Maddox Lake near the KOA, Howenwald (35.435486°N, 87.469549°W; WSG 84). 25 July 2013. Sommer Smith and Nicole Foster. Verified by A. Floyd Scott. Austin Peay State University (APSU 19489). New county record (Scott. and Redmond 2008 [latest update: 9 January 2014]. Atlas of Reptiles in Tennessee. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/, accessed 20 April 2014).

SOMMER SMITH (e-mail: ssmith71@Columbiastate.edu), and **NICOLE FOSTER**, Department of Biology, Columbia State Community College, Columbia, Tennessee 38401, USA (e-mail: nfoster2@Columbiastate.edu).

***CHELYDRA SERPENTINA* (Snapping Turtle)**. USA: GEORGIA: Emanuel Co.: Adrian (32.51183°N, 82.59066°W; WGS 84). 9 March 2014. Chris Murphy, Will Booker, Bridget Altman. Verified by Nikole Castleberry. Georgia Museum of Natural History (GMNH 50675 photo voucher). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens. 575 pp.). *Chelydra serpentina* had been previously observed in Emanuel Co. but was unvouchered. This individual was found in an inflow stream to a man-made pond near the road.

CHRIS MURPHY, Warnell School of Forestry and Natural Resources, University of Georgia, Athens, Georgia 30609, USA; e-mail: chris987@uga.edu.

***CHRYSEMYS PICTA BELLI* (Western Painted Turtle)**. USA: IDAHO: Madison Co.: Henry's Fork of the Snake River, near Rexburg (43.866337°N, 111.865172°W; WGS 84). 13 September 2010. Caleb L. Loughran. Verified by David M. Darda. CWU Herpetology Collection 14-001, photo voucher. New county record (Groves et. al. 1997. Atlas of Idaho's Wildlife. Idaho Fish and Game, Nongame and Endangered Wildlife Program, Boise, Idaho. 411 pp.). Likely unrecorded distribution of introduced populations in southeastern Idaho (Barela and Olson 2014. Northwest. Nat. 95:1–12).

CALEB L. LOUGHRAN (e-mail: loughranc@cwu.edu), and **ROBERT E. WEAVER** (e-mail: weaverro@cwu.edu), Department of Biological Sciences, Central Washington University, Ellensburg, Washington 98926, USA.

***GRAPTEMYS ERNSTI* (Escambia River Map Turtle)**. USA: FLORIDA: Orange Co.: Wekiwa Springs State Park, approximately 150 m downstream at the edge of the Wekiwa Springs lagoon and the start of the Wekiwa Springs run (28.714071°N, 81.458624°W, WGS84; elev. 6 m). 6 June 2014. Joanne Bolemon and Eric C. Munscher. Verified by Kenneth L. Krysko. Florida Museum of Natural History (UF 173444). New county record (Krysko et al.

2011. Atlas of Amphibians and Reptiles in Florida. Final Report, Florida Fish and Wildlife Conservation Commission, Tallahassee, Florida. 524 pp.).

Adult male observed basking on a log around 1000 h. The abundance of algae on the carapace (75% of surface area) suggests this is not a recently released captive. This is the first reported occurrence of *G. ernsti* in the St. Johns River Basin. This species is native to Florida in the extreme western panhandle over 300 miles distant. Even though this particular species is not sold as frequently in the pet trade as the Red-eared Slider (*Trachemys scripta elegans*) and the False Map Turtle (*Graptemys pseudogeographica pseudogeographica*) it is possible that this animal was a released pet. Wekiwa Springs State Park provides suitable habitat for this species. *Graptemys ernsti* could potentially thrive in such a diverse and turtle-rich ecosystem.

ERIC C. MUNSCHER, Department of Natural Resources, SWCA Environmental Consultants, Houston, Pennsylvania 15017, USA (e-mail: emunscher@swca.com); **JOANNE BOLEMON**, Casselberry, Florida 32707, USA (e-mail: jobol@embarqmail.com).

***GRAPTEMYS GEOGRAPHICA* (Northern Map Turtle)**. USA: TENNESSEE: Hardin Co.: Horse Creek (35.116669°N, 88.157236°W; WGS84). 1 May 2014. Brian P. Butterfield, Lisa M. Raine, and M. Rachel Hobgood. Verified by A. F. Scott. Austin Peay State University (APSU 19490 photographic voucher). New county record (Scott and Redmond 2008 [latest update: 10 March 2014]. Atlas of Reptiles in Tennessee. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/), accessed 5 May 2014.

BRIAN P. BUTTERFIELD (e-mail: bbutterfield@fhu.edu), and **LISA M. RAINE, M. RACHEL HOBGOOD**, Department of Biological, Physical, and Human Sciences, Freed-Hardeman University, Henderson, Tennessee 38340, USA.

***KINOSTERNON INTEGRUM* (Mexican Mud Turtle)**. MÉXICO: OAXACA: Municipality of Ixtlán de Juárez: border road near Universidad de la Sierra Juárez–Ixtlán (17.316798°N, 96.483373°W; WGS84), 1938 m elev. 3 August 2008. Victor Aguirre Hidalgo and Miriam Illescas Aparicio. Verified by Víctor Hugo Reynoso. Colección Herpetofaunística, Universidad de la Sierra Juárez - Ixtlán (ICAH 141). First record for the municipality and Sierra de Juarez in Oaxaca, extending the know range of this species 45.9 km SW from the nearest known locality at Zoquiapan Boca de los Ríos, Oaxaca (Canseco-Márquez and Gutiérrez Mayen 2010. Anfibios y Reptiles del Valle Tehuacán-Cuicatlán. CONABIO, Cuicatlán, A.C., Benemérita, Univ. Autón. de Puebla, México, D.F. xvi + 302 pp.). This locality also extends the known elevation of the species by 208 m (Canseco-Márquez and Gutiérrez 2010, *op. cit.*). The turtle was DOR in an area originally covered by riparian vegetation.

VICTOR AGUIRRE-HIDALGO (e-mail: victor@juppa.unsij.edu.mx), and **MIRIAM ILLESCAS-APARICIO,** Instituto de Estudios Ambientales, Universidad de la Sierra Juárez, Avenida Universidad S/N, Ixtlán de Juárez, Oaxaca, México, CP 68725 Oaxaca; **ADRIANA J. GONZÁLEZ-HERNÁNDEZ**, Colección Nacional de Anfibios y Reptiles. Instituto de Biología. Departamento de Zoología, UNAM, México D.F. 04510, México.

***KINOSTERNON SUBRUBRUM* (Eastern Mud Turtle)**. USA: TENNESSEE: Chester Co.: Henderson, Freed-Hardeman University (35.434725°N, 88.634°W; WGS84). 15 April 2014. Brian Butterfield, Rachel Hobgood, Eric Hughes, and Joshua Kee. Verified by A. F. Scott. Austin Peay State University (APSU 19486 color photos). New county record (Scott and Redmond 2008 [latest update: 10 March 2014]. Atlas of Reptiles in Tennessee. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/, accessed 17 April 2014. Adult female captured in a baited hoop net.

BRIAN P. BUTTERFIELD (e-mail: bbutterfield@fhu.edu), **M. RACHEL HOBGOOD**, **ERIC A. HUGHES**, **JOSHUA P. KEE**, and **LEE J. BARTON**, Department of Biological, Physical, and Human Sciences, Freed-Hardeman University, Henderson, Tennessee 38340, USA.

***MALACLEMYS TERRAPIN* (Diamond-backed Terrapin)**. USA: LOUISIANA: Calcasieu Parish: Tidally-influenced, brackish marsh near Turner Bay (30.064848°N, 93.306107°W; WGS84), 4.25 km S of the Calcasieu Point boat launch. 30 April 2014. Will Selman and Chance Baccigalopi. Verified by Peter Lindeman. Florida Museum of Natural History Herpetology Department photographic archive (UF 173242). New parish record (Dundee and Rossman 1989. The Reptiles and Amphibians of Louisiana. Louisiana State University Press, Baton Rouge, Louisiana. 300 pp.; Selman et al., *in press*, Chelon. Conserv. Biol.; HerpNet2 Database search, www.herpnet2.org, accessed 14 May 2014). This record extends the range of *M. terrapin* in the Calcasieu River estuary approximately 21 km N of existing records from east side of Sabine National Wildlife Refuge (Selman et al., *op. cit.*). Individual captured in an unbaited fyke net.

WILL SELMAN (e-mail: wselman@wlf.la.gov) and **CHANCE BACCIGALOPI**, Rockefeller Wildlife Refuge, Louisiana Department of Wildlife and Fisheries, 5476 Grand Chenier Hwy, Grand Chenier, Louisiana 70643, USA.

***PSEUDEMYS CONCINNA* (River Cooter)**. USA: TENNESSEE: Chester Co.: Henderson, Freed-Hardeman University (35.434725°N, 88.634°W; WGS84). 8 May 2014. Brian Butterfield, Rachel Hobgood, Eric Hughes, and Joshua Kee. Verified by A. F. Scott. Austin Peay State University (APSU 19491 color photos). New county record (Scott and Redmond 2008 [latest update: 10 March 2014]. Atlas of Reptiles in Tennessee. Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/, accessed 8 May 2014.). Juvenile captured in a baited hoop net.

BRIAN P. BUTTERFIELD (e-mail: bbutterfield@fhu.edu), **JOSHUA P. KEE**, **M. RACHEL HOBGOOD**, and **ERIC A. HUGHES**, Department of Biological, Physical, and Human Sciences, Freed-Hardeman University, Henderson, Tennessee 38340, USA.

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle)**. USA: ARKANSAS: Calhoun Co.: Locust Bayou off St. Hwy 278 at Locust Bayou (33.557668°N, 92.67574°W; WGS 84). 8 April 2014. Verified by S. E. Trauth. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 33106). New county record filling a gap among previous records for adjacent Dallas, Ouachita, and Union counties (Trauth et al. (2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville, Arkansas. 421 pp.)

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); **HENRY W. ROBISON**, 9717 Wild Mountain Drive, Sherwood, Arkansas 72120, USA (e-mail: hwrobison@yahoo.com).

***STERNOTHERUS ODORATUS* (Eastern Musk Turtle)**. USA: TEXAS: Montgomery Co.: Peach Creek, 3.5 km S of Splendora (30.20743°N, 95.18189°W, WGS84; elev. 21 m). 26 May 2013.

William L. Farr. Verified by Carl J. Franklin. UTADC 8059–8061. The first county record, partially filling a distributional gap in the greater Houston area of southeast Texas (Dixon 2013. Amphibians and Reptiles of Texas with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. 3rd ed., Texas A&M University Press, College Station, Texas. 447 pp.) and apparently the first record from the San Jacinto River drainage (Iverson 1992. A Revised Checklist with Distribution Maps of the Turtles of the World. Green Nature Books, Homestead, Florida. 363 pp.).

The turtle, an adult male ca. 10 cm in straight carapace length, was observed at 1307 h in clear water ca. 5–10 cm deep where it was caught, examined, photographed, and released. A leach, ca. 25 mm in length, was attached at the seam of the 9th and 10th marginals on the left underside of the carapace. Also of note, Dixon 2013 (*op. cit.*) does not indicate a record for neighboring Harris Co., Texas; however, the specimen illustrated in that same volume is identified as being from Harris Co. I recall observing and collecting *S. odoratus* in roadside ditches, creeks, and ponds in Harris Co. with some regularity in the 1970s; these were distinguished from the sympatric *Kinosternon subrubrum* (Eastern Mud Turtle) by the reduced plastron size, lacking two conspicuous hinges.

WILLIAM L. FARR, Houston, Texas 77096, USA; e-mail: williamfarr@sbcglobal.net.

***TERRAPENE CAROLINA TRIUNGUIS* (Three-toed Box Turtle).** USA: ARKANSAS: Cleveland Co.: off St. Hwy. 189, 14.5 km SE of Kingsland (33.772296°N, 92.173963°W; WGS 84). 23 April 2014. H. W. Robison. Verified by S. E. Trauth. Arkansas State University Museum of Zoology, Herpetological Collection (ASUMZ 33152, photovoucher). New county record filling a gap among previous records for adjacent Lincoln (Connior 2013. Herpetol. Rev. 43:444), and Bradley, Calhoun, Dallas, Grant, and Jefferson counties (Trauth et al. (2004. Amphibians and Reptiles of Arkansas. Univ. Arkansas Press, Fayetteville, Arkansas. 421 pp.).

CHRIS T. McALLISTER, Science and Mathematics Division, Eastern Oklahoma State College, Idabel, Oklahoma 74745, USA (e-mail: cmcallister@se.edu); **HENRY W. ROBISON**, 9717 Wild Mountain Drive, Sherwood, Arkansas 72120, USA (e-mail: hwrobison@yahoo.com).

***TRACHEMYS SCRIPTA* (Pond Slider).** USA: MISSOURI: Ste. Genevieve Co.: Weingarten. Found on roadside at intersection of Glassey Lane and Highway 32 (37.8620°N, 90.2695°W; WGS84). 27 April 2014. Andrew P. Braun and Andrew T. Bueltmann. Verified by Dustin S. Siegel. University of Missouri-Columbia (UMC 2601P). New county record (Edmond and Daniel 2014 [latest update: 18 February 2014]. Missouri Herpetological Atlas Project. Available at http://atlas.moherp.org/; accessed 4 June 2014). Roadkilled female specimen.

ANDREW P. BRAUN (e-mail: Andrew.Braun@mdc.mo.gov), and **ANDREW T. BUELTMANN**, Big Rivers & Wetlands Field Station, Missouri Department of Conservation, Jackson, Missouri 63755, USA.

***TRACHEMYS SCRIPTA ELEGANS* (Red-eared Slider).** USA: NEW MEXICO: Lea Co.: Conoco Lake, along an unnamed road ca. 4.0 road miles SE of Maljamar, (32.80973°N, 103.75061°W, NAD 83; elev. 1201 m). 3 July 2013. Austin L. Fitzgerald and Charles W. Painter. Verified by Tom Giermakowski. Museum of Southwestern Biology, University of New Mexico (MSB 95060 and 95074). New county record (Degenhardt et al. 1996. Amphibians and Reptiles of New Mexico. Univ. New Mexico Press, Albuquerque, New Mexico. xix + 431 pp.). Two adult females (204 mm and 195 mm SCL) were captured using hoop traps baited with sardines. Both individuals were preserved at time of capture. This locality is a small pond separated from the nearest known locality of native Red-eared Sliders by at least 50 km of arid habitat. These specimens may represent intentionally released individuals.

AUSTIN L. FITZGERALD (e-mail: austinl.fitzgerald@gmail.com) and **CHARLES W. PAINTER**, University of New Mexico, Museum of Southwestern Biology, MSC03 2020, University of New Mexico, Albuquerque, New Mexico 87131, USA (e-mail: cwpainter49@gmail.com).

SQUAMATA — LIZARDS

***CYTOPODION SCABRUM* (Rough-tailed Bowfoot Gecko).** USA: ARIZONA: Maricopa Co.: 7200 E. University Drive, Mesa (33.423530°N, 111.675416°W, WGS84; elev. 403 m). Four specimens collected between 3 April (UAZ 57586, UAZ 57587) and 7 April 2014 (UAZ 57588, UAZ 57589). Verified by Aaron Bauer. New record for the state (Brennan and Holycross 2009. Amphibians and Reptiles in Arizona. Arizona Game and Fish Department, Phoenix, Arizona. 150 pp.).

Several individuals of *Cyrtopodion* had been sighted and two sets of hatched eggs found, however both were initially mistaken for *Hemidactylus turcicus*. It was not until a lizard was captured and examined closely that it was recognized as something different. A nighttime survey of the building exteriors on 12 April 2014 revealed an established population (N = 47) with nearly all size classes (10–53 mm SVL) represented. The geckos were generally located clinging to walls from a few cm above ground to over 5 m up. They seemed to avoid well-lit areas and a few specimens were located on curbs and on large rocks in the landscaping.

Though it is unclear how this species came to be established here, there are two obvious potential pathways for introduction. The pet trade is the primary source for the introduction of exotic reptiles and amphibians in the United States (Kraus 2009. Alien Reptiles and Amphibians: A Scientific Compendium and Analysis. Springer Science and Business Media B.V., Dordrecht, Netherlands. 563 pp.). But this seems the least likely of the two scenarios imagined. Another far more probable avenue for this species' introduction is as a stowaway in cargo. The collection locality is adjacent to a large industrial complex (Salt River Project) that receives shipments of heavy equipment such as generators from a variety of localities. Kraus (*op. cit.*) cites stowing away in cargo as the second most common way that exotic reptile species are introduced in the United States.

Photos taken in mid-April 2014 of *C. scabrum* from the US Air Force Auxiliary Field in Gila Bend, Maricopa Co., Arizona were forwarded to me by Richard K. Whittle, Biologist, 56th Range Management Office, Phoenix, Arizona. Mr. Whittle stated that he had seen geckos on auxiliary buildings since 2010 but is uncertain if they were this species. The general similarity in appearance and behavior of *C. scabrum* to *Hemidactylus turcicus*, an abundant, secretive, and widespread exotic, makes it easy to overlook. *Cyrtopodion scabrum* differs from *H. turcicus* in many ways, the most obvious of these being the absence of toe pads. *Cyrtopodion scabrum* may be much more widespread in the United States than previous reports indicate. Its nocturnal activity, apparent avoidance of lighted areas, and habit of sheltering in secluded refugia during daylight hours make it easy to overlook. Geckos encountered on buildings should be subjected to close examination to determine species.

Cyrtopodion scabrum is native to the Middle East including Pakistan, Afghanistan, Iraq, Iran, and Turkey. Considering all the

time the USA has been spending in this part of the world in recent decades it is not surprising a species commonly associated with anthropogenic structures such as urbanized areas and shipping yards has made its way to the United States. This species is established in Galveston, Texas, USA (Selcer and Bloom 1984. Southwest. Nat. 29:499–500).

RANDALL D. BABB, Arizona Game and Fish Department, Region VI Office, 7200 E. University Dr., Mesa, Arizona 85207, USA; e-mail: rbabb@azgfd.gov.

***DASIA OLIVACEA* (Olive Tree Skink)**. THAILAND: SONGKHLA PROVINCE: Hat Yai District: Ton Nga Chang Wildlife Sanctuary, Headquarters (6.9456°N, 100.2395°E, WGS 84; ca. 160 m elev.). At daytime, adult (lacking yellow bands on dorsum) observed on tree trunk; juvenile observed on ground. Tanet Siangsuwan. 31 July 2013. Khon Kaen University Vertebrate Collection (KKUD 2014.1a–b, 2014.2a–b). Verified by Sunchai Makchai. First provincial record for Songkhla Province; fills distributional gap between Pattani, and Satun provinces. Previously known from the west (Kanchanaburi), northeast (Nakhon Ratchasima), southeast (Chanthaburi, Srakaeo), and south (Nakhon Sri Thammarat, Narathiwat, Pattani, Phangnga, Phuket, Satun, Surat Thani, Trang, Yala) of Thailand (Chuaynkern and Chuaynkern 2012. J. Wildl. Thailand 19:75–162).

We thank Khon Kaen University Vertebrate Collection for cataloging the record in the Digital Photograph Collection (KKUD). Our special thanks to KKU Herpetological Research Group for supporting this work.

QUINTERO-DÍAZ**, Universidad Autónoma de Aguascalientes, Centro de Ciencias Básicas, Departamento de Biología, Avenida Universidad No. 940, Aguascalientes, Aguascalientes 20131, México.

***EMOIA RUFICAUDA* (Red-tailed Swamp Skink)**. PHILIPPINES: MINDANAO ISLAND: SOUTH COTABATO PROVINCE: Municipality of Lake Sebu: Barangay Lake Seloton (6.255775°N, 124.733772°E, WGS 84; ca. 400 m elev.). 22 September 2013. Jeniel Buday. Photographic voucher, Raffles Museum of Biodiversity Research, National University of Singapore (ZRC [IMG] 2.219a–b). Verified by Rafe M. Brown. Observed on riverbank of Seven Falls. First provincial record. Endemic to Mindanao Island, previously recorded from provinces of Agusan del Norte, Sarangani, Sultan Kudarat, and Zamboanga del Sur (Gaulke and Alcala 2009. Salamandra 45:57–60). Record extends distribution by ca. 31 km NE from nearest locality at Maitum, Sarangani.

EMERSON Y. SY, Philippine Center for Terrestrial and Aquatic Research, 1198 Benavidez St., Unit 1202, Tondo, Manila, Philippines (e-mail: emersonsy@gmail.com); **JENIEL BUDAY**, Wild Bird Photographers of South Cotabato, Koronadal City, South Cotabato, Philippines.

***GERRHONOTUS INFERNALIS* (Texas Alligator Lizard)**. USA: TEXAS: Terrell Co.: Independence Creek Preserve TNC on a road traversing a steep limestone hillside (30.49722°N, 101.78901°W, WGS 84; elev. 2380 m). 13 April 2014. Michael T. Sager. Verified by John Karges and Travis LaDuc. University of Texas at Arlington Amphibian and Reptile Diversity Research Center (Digital Image Collection Number UTADC 8125, photographic voucher). New county record. Previous records exist for Brewster Co. to the west, and Crockett Co. and Val Verde Co. to the east. This record fills the gap bridging these counties.

This animal was found during the Texas Herpetological Society's spring field meeting. The individual was collected active on the surface on a cool, damp, early morning after a night of light but steady rain. Found along a rocky north-facing hillside with open juniper woodlands with some shrubs and grass cover among barren rock ledges and boulders, this juvenile is evidence of a breeding/viable population.

MICHAEL T. SAGER, Department of Biological Sciences, MS 43131, Texas Tech University, Lubbock, Texas 79409-3131, USA; e-mail: michael.sager@ttu.edu.

***HELODERMA SUSPECTUM CINCTUM* (Banded Gila Monster)**. USA: NEVADA: Clark Co.: Lucy Gray Mountains (35.6384°N, 115.3074°W; WGS 84). 24 May 2010. David B. Prival. Verified by C. Mahrdt. Natural History Museum of Los Angeles County voucher photograph (LACM-PC 1604). New record for the species in Nevada; extends range westward ca. 13 km from records in the McCullough Mountains (18 May 2012: 35.7520°N, 115.1499°W; WGS 84; 24 May 2012:35.7586°N, 115.1489°W; WGS 84).

The Lucy Gray Mountains are ca. 32 km E of a known record of *Heloderma* in California (UNLV R665, Lovich and Beaman 2007. Bull. So. California Acad. Sci. 106[2]:39–58) and ca. 40 km from a sight record (no vouchers available) from the New York Mountains (Stebbins and Cohen 2012. Field Guide to Amphibians and Reptiles of California, University of California Press, Berkeley, California. 538 pp.). The close proximity of these records to known locations of *Heloderma* in California suggests a dispersal route from the Colorado River area into southeastern California (as suggested by Lovich and Beaman, *op. cit.*), possibly through mountain passes that may serve as corridors between areas of suitable habitat.

***HEMIDACTYLUS FRENATUS* (Common House Gecko)**. MÉXICO: TABASCO: Municipality of Macuspana: Holcim-Apasco Field Station (17.65156°N, 92.438858°W; WGS84), 40 m elev. 9 June 2014. Pierre Charruau, Rafael A. Lara-Resendiz, and Aníbal H. Díaz de la Vega-Pérez. Verified by F. Méndez-de la Cruz. CNAR-RF 62-64. First municipality record, extending the range ca. 65 airline km SE from Villahermosa, Municipality of Centro, Tabasco (Schmidt-Ballardo and Mendoza-Quijano 1996. Herpetol. Rev. 27:40; Farr 2011. Southwest. Nat. 56: 256–273). The gecko was found on the wall of a cabin in tropical rain forest.

ANÍBAL H. DÍAZ DE LA VEGA-PÉREZ (e-mail: anibal.ahelios@gmail.com), **RAFAEL A. LARA-RESENDIZ** (e-mail: rafas.lara@gmail.com), and **PIERRE CHARRUAU** (e-mail: charruau_pierre@yahoo.fr), Laboratorio de Herpetología, Instituto de Biología, Universidad Nacional Autónoma de México, AP 70515, CP 04510, Distrito Federal, México.

***HEMIDACTYLUS TURCICUS* (Mediterranean Gecko)**. USA: CALIFORNIA: San Bernardino Co.: Redlands, State Street, between Center Street (34.03429°N, 117.11466ºW; WGS 84) and Eureka Street (34.03397°N, 117.11176°W; WGS 84), and on Brookside Avenue (34.03276°N, 117.11242°W; WGS 84). 18 August 2013. Kent R. Beaman and Michael D. Wilcox. Verified by Clark Mahrdt. Nine individuals representing adults (N = 4) and juveniles (N = 5) were deposited in the herpetological collections at the Natural History Museum of Los Angeles County (LACM 148427–148435). Represents the third record for San Bernardino Co. (Beaman et al. 2005. Herpetol. Rev. 36:79), extending the range of the species ca. 356 km WSW from the nearest vouchered locality at Needles, San Bernardino Co., California (LACM 155124). The species was also observed at several other locations in Redlands.

MICHAEL D. WILCOX, AMEC Environment and Infrastructure, Inc., 3120 Chicago Avenue, Suite 110, Riverside, California 90507, USA (e-mail: michael.wilcox@amec.com); **KENT R. BEAMAN**, Section of Herpetology, Natural History Museum of Los Angeles County, 900 Exposition Blvd., Los Angeles, California 90007, USA and Department of Biology, La Sierra University, Riverside, California 92515, USA (e-mail: heloderma@roadrunner.com).

***LYGOSOMA ALBOPUNCTATA* (White-spotted Supple Skink)**. BANGLADESH: SYLHET DIVISION: Habiganj District: Satchari National Park (24.143653°N, 91.438686°E, WGS 84; 80 m elev.). 25 April 2014. Adult. Hassan-Al-Razi. Yard of Student Dormitory, Satchari National Park. Verified by Stephen Mahony. Museum of Zoology, Jagannath University, Dhaka, Bangladesh (JnU/ZooM/Rep/2014/0001). First record for Sylhet Division. Nearest confirmed populations from Berakuti (Nilphamari), Singra National Park (Dinajpur), and Rayer Bazar fish market (Dhaka District) (Sarker 2014. Russ. J. Herpetol. 21:1–4). The new record 135 km E from Nilphamari, 130 km E of Dinajpur, and 130 km NE of Dhaka District. Habitat dry, open soil, without plantations, near human-modified habitat.

HASSAN-AL-RAZI, Department of Zoology Jagannath University, Dhaka 1100, Bangladesh (e-mail: chayan1999@yahoo.com); **MOHAMMAD ABDUL BAKI**, Department of Zoology, Jagannath University, Dhaka 1100, Bangladesh (e-mail: mabaki@gmail.com); **SHAYER MAHMOOD IBNEY ALAM**, Department of Zoology, Jagannath University, Dhaka 1100, Bangladesh (e-mail: shayermia@hotmail.com); and **MEHRAB CHOWDHURY**, Department of Zoology, Jagannath University, Dhaka 1100, Bangladesh (e-mail: mehrab45@hotmail.com).

***PHRYNOSOMA BRACONNIERI* (Short-tailed Horned Lizard)**. MÉXICO: GUERRERO: Municipality of Olinala: Xixila (17.993334°N, 98.850278°W; WGS84), 1535 m. elev. 15 October 2011. Víctor Hugo Jiménez Arcos, Salomón Sanabria Urban, and Eric Centenero Alcalá. Verified by Luis Canseco Márquez. IBH-RF 53. First record for Guerrero, extending the known range of the species ca. 70 km SW from Tehuitzingo, Puebla (Garcia-Vazquez et al. 2005. Publ. Soc. Herpetol. Mex. 1:152–169). The lizard was found active on the ground in oak forest.

***PLESTIODON FASCIATUS* (Common Five-lined Skink)**. USA: MISSOURI: Ste. Genevieve Co.: Weingarten, 1.15 km NE of intersection of Miller Switch Road and Highway 32 (37.8656°N, 90.2588°W; WGS84). 3 May 2014. Andrew P. Braun and Andrew T. Bueltmann. Verified by Dustin S. Siegel. University of Missouri-Columbia (UMC 2598P). New county record (Edmond and Daniel 2014 [latest update: 18 February 2014]. Missouri Herpetological Atlas Project. Available at http://atlas.moherp.org/; accessed 4 June 2014). Adult in rocky upland habitat.

ANDREW P. BRAUN (e-mail: Andrew.Braun@mdc.mo.gov) and **ANDREW T. BUELTMANN**, Big Rivers & Wetlands Field Station, Missouri Department of Conservation, Jackson, Missouri 63755, USA.

***PLESTIODON FASCIATUS* (Common Five-lined Skink)**. USA: WISCONSIN: Chippewa Co.: City of Chippewa Falls (44.93854°N, 91.3879°W, WGS84; elev. 256 m). 17 May 2014. Tiffany J. Wogahn. Verified by Robert C. Jadin. UTADC 8161. New county record (Christoffel et al. 2002. Turtles and Lizards of Wisconsin. Wisconsin Department of Natural Resources, Bureau of Endangered Resources; 48 pp.) Closest known record is in Eau Claire Co. to the south. In Wisconsin, *P. fasciatus* is a Species of Special Concern and has a scattered distribution. The lizard was found in a residential yard.

TIFFANY J. WOGAHN, 116 N. Grove Street, Chippewa Falls, Wisconsin 54729, USA; **JULIE M. RAY**, La MICA Biological Station, El Copé de La Pintada, Coclé Province, Republic of Panama (e-mail: teamsnakepanama@gmail.com).

***PLESTIODON INEXPECTATUS* (Southeastern Five-lined Skink)**. USA: GEORGIA: Lamar Co.: Private residence on Grape Creek Road in Milner (33.108610°N, 84.221679°W; WGS 84). 21 April 2014. Olivia Bender and M. J. Bender. Verified by Gregory D. Hartman. Gordon State College (GSC-066). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.; J. Jensen, pers. comm.). Species has been documented in two adjoining counties (Jensen et al. 2008).

Specimen collected under a Georgia Department of Natural Resources Scientific Collections Permit (29-WJH-14-159).

MICHAEL J. BENDER, Gordon State College, 419 College Drive, Barnesville, Georgia 30204, USA; e-mail: mbender@gordonstate.edu.

***PLESTIODON TETRAGRAMMUS BREVILINEATUS* (Short-lined Skink)**. USA: TEXAS: Archer Co.: North–south oriented sandstone outcrop 6 km NNE of the town of Olney (33.431389°N, 98.733889°W, WGS 84; elev. 375 m). 25 March 2013. Matthew R. Fox. Verified by Raymond E. Willis. The University of Texas at Arlington's Amphibian and Reptile Diversity Center (UTADC 8112, photo voucher). New county record (Dixon 2013. Amphibians and Reptiles of Texas with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. 3rd ed., Texas A&M University Press, College Station, Texas. 447 pp.). Extends range north and east from bordering Young, Throckmorton, and Baylor counties. Adult male specimen, SVL 66 mm, weight 6.6 g, was found under a flat rock on the east-facing side of the outcrop.

MATTHEW R. FOX (e-mail: matthew.fox.0906@students.mwsu.edu), **ROBERT W. STEWART**, and **CHARLES M. WATSON,** Department of Biology, Midwestern State University, Wichita Falls, Texas 76308, USA.

***STENOLEPS RIDLEYI* (Pernambuco Teiid)**. BRAZIL: ALAGOAS: Municipality of Murici: Estação Ecológica de Murici, Mata da Bananeira (9.215888°S, 35,878915°W, WGS84; elev. 583 m). 12 December 2013. J. V. Araújo-Neto and others. Coleção Herpetológica do Museu de História Natural, Universidade Federal de Alagoas, Maceió, Brazil (Mufal 11686; collecting license ICMBio 33507-3). Verified by B. S. Lisboa. The species was previously recorded from Brazilian states of Pernambuco and Ceará (Vanzolini 1974. Papéis Avulsos Zoologia 18 [4] 61-90; Borges-Nojosa and Caramaschi 2003. *In* Leal and Tabarelli [eds.], Ecologia e Conservação da Caatinga, pp. 489–540. UFPE, Recife; Rodrigues et al. 2007. Am. Mus. Novit. 3465:1–27). First state record. The new record extends the known geographic distribution about 100 km S from the locality of Serra dos Cavalos, Pernambuco state (Rodrigues 1990. *In* Waranabe [ed.], II Simpósio sobre Ecossistemas da Costa Sul e Sudeste Brasileira, pp. 404–410. Academia de Ciências do Estado de São Paulo, São Paulo), and represents a new southern limit of species distribution.

***VARANUS RASMUSSENI* (Rasmussen's Water Monitor Lizard)**. PHILIPPINES: SULU PROVINCE: JOLO ISLAND: Municipality of Talipao: Mount Bayug (5.974600°N, 121.083983°E; WGS 84). Romulo Quemado. 7 February 2014. Photographic voucher, Raffles Museum of Biodiversity Research, National University of Singapore (ZRC [IMG] 2.221a–f); Bitinan Island, Municipality of Omar (6.056700°N, 121.445650°E; WGS 84). 5 October 2013. Romulo Quemado. Photographic voucher, Raffles Museum of Biodiversity Research, National University of Singapore (ZRC [IMG] 2.222). Verified by Luke J. Welton. First record for Jolo and Bitinan islands, Sulu Archipelago. Member of the *Varanus salvator* complex, described recently from Tawi-Tawi Island, Sulu Archipelago, Philippines (Koch et al. 2010. Zootaxa 2446:1–54).

EMERSON Y. SY, Philippine Center for Terrestrial and Aquatic Research, 1198 Benavidez St., Unit 1202, Tondo, Manila, Philippines (e-mail: emersonsy@gmail.com); **ROMULO QUEMADO**, Philippine Marine Corps, Western Command Headquarters, Puerto Princesa City, Palawan, Philippines.

SQUAMATA — SNAKES

***ARIZONA ELEGANS ARENICOLA* (Texas Glossy Snake)**. USA: TEXAS: Colorado Co.: Cat Spring Rd., 21 km ENE of Columbus (29.79052°N, 96.34370°W, WGS84; elev. 83 m). 31 May 2014. William L. Farr. Verified by Carl Franklin. University of Texas Arlington Digital Collection (UTADC 8162–8167). First county record, with previous records for two (Austin to the NE and Fayette to the NW) of the five adjacent counties having been documented (Dixon 2013. Amphibians and Reptiles of Texas with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. 3rd ed., Texas A&M University Press, College Station, Texas. 447 pp.).

WILLIAM L. FARR, Houston, Texas 77096, USA (e-mail: williamfarr@sbcglobal.net); **MICHAEL R. J. FORSTNER**, Texas State University, Department of Biology, 601 University Drive, San Marcos, Texas 78666, USA (e-mail: MF@txstate.edu).

***CARPHOPHIS AMOENUS* (Common Wormsnake)**. USA: TENNESSEE: Hickman Co.: 9137 Betty Belle Lane, Bon Aqua (35.9248477°N, 87.2301613°W; WSG 84). 20 April 2014. Nicole Foster and Mary Christensen. Verified by A. Floyd Scott. Austin Peay State University (APSU 19488). Found among leaf litter. New county record (Scottand Redmond 2008 [latest update: 09 January 2014]. Atlas of Reptiles in Tennessee. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/, accessed 20 April 2014).

NICOLE FOSTER (e-mail: nfoster2@Columbiastate.edu), and **MARY CHRISTENSEN**, Columbia State Community College, Columbia, Tennessee 38401, USA (e-mail: diz1647@yahoo.com).

***CARPHOPHIS VERMIS* (Western Wormsnake)**. USA: ARKANSAS: Ashley Co.: Carter Cemetery, 13 km NE Crossett off AR St. Hwy 52 (33.16966°N, 91.83768°W; WSG84). 21 May 2014. R. Tumlison. Henderson State University (HSU 1730). Verified by S. E. Trauth. First county record and only the second county in a disjunct southeastern Arkansas population (Trauth et al. 2004. The Amphibians and Reptiles of Arkansas. University of Arkansas Press, Fayetteville, Arkansas. 421 pp.). Range is extended about 50 km S from nearest Arkansas record (Tumlison and Wiley 1980. Herpetol. Rev. 11:14–15). Record also appears to connect disjunct

southeastern Arkansas population with similar records in northeastern Louisiana, from which this record extends the range about 45 km N from Morehouse Parish, Louisiana (Dundee and Rossman 1989. The Amphibians and Reptiles of Louisiana. Louisiana State University Press, Baton Rouge, Louisiana. 300 pp.).

RENN TUMLISON, Department of Biology, Henderson State University, Arkadelphia, Arkansas 71999, USA; e-mail: tumlison@hsu.edu.

***CLONOPHIS KIRTLANDII* (Kirtland's Snake)**. USA: ILLINOIS: De Kalb Co.: 1.5 mi (2.4 km) W Sandwich (41.635637°N, 88.654220°W; WGS 84). 8 October 1961. H. D. Walley. MSUM 14207. Verified by Chris Phillips. New county record (Phillips et al. 1999. Field Guide to Amphibians and Reptiles of Illinois. Illinois Natural History Survey, Urbana, Illinois. 282 pp.). The alcohol specimen was found in the Michigan State University Museum herpetology collection during an examination of material from the upper peninsula of Michigan. This Illinois state-threatened species was most recently documented from McLean Co. (Capparella et al. 2012. Trans. Illinois State Acad. Sci. 105(3–4):101–105), and this record is the northwestern-most in the state to date.

THOMAS G. ANTON, Division of Amphibians and Reptiles, The Field Museum, Roosevelt Road at Lakeshore Drive, Chicago, Illinois 60614, USA (e-mail: TomAnton@comcast.net); **THOMAS F. BEAUVAIS**, P.O. Box 130137, Ann Arbor, Michigan 48113, USA; **GARY CASPER,** The University of Wisconsin-Milwaukee Field Station, P.O. Box 375, Slinger, Wisconsin 53086, USA.

***DIADOPHIS PUNCTATUS* (Ring-necked Snake)**. USA: CALIFORNIA: Kern Co.: Piute Mountains., Cottonwood Creek watershed, approx. 13.7 air mi. W jct. Jawbone Canyon Rd. × State Hwy 14 (35.30383°N, 118.25253°W, WGS 84; elev. 1364 m). 02 June 2010. L. E. Hunt and C. J. Evelyn. Verified by Samuel S. Sweet. University of California-Santa Barbara, Vertebrate Museum collection 32724. Second record for eastern slope of Sierra Nevada (Hansen and Tobler 2010. Herpetol. Rev. 41:379). Nearest record is from Kern Co., Mill Creek, 1.1 mi E State Hwy 178 (CAS 236215), 42 airline km to the NW. Present specimen is an adult female encountered AOR on dirt road at 1645 h in closed-canopy Interior Live Oak woodland.

CHRISTOPHER J. EVELYN, Department of Evolutionary and Marine Biology, University of California, Santa Barbara, California 93106, USA (e-mail: christopher.evelyn@lifesci.ucsb.edu); **LAWRENCE E. HUNT,** Hunt & Associates Biological Consulting Services, 5290 Overpass Road, Suite 108, Santa Barbara, California 93111, USA (e-mail: anniella@verizon.net).

***DIADOPHIS PUNCTATUS REGALIS* (Regal Ringneck Snake)**. MEXICO: SONORA: Municipio de la Colorada: Rancho La Cuesta, Km 94 on Mexico Hwy 16, 24.9 km (by air) W of Tecoripa, 80 km (by air) ESE of Hermosillo (28.6269400°N, 110.20667°W; NAD27), 410 m elev. 6 August 2009. Juan Jaime. Verified by Erik F. Enderson. Photographic voucher can be viewed at <http://www.madrean.org/symbfauna/collections/individual/index.php?occid=198334>. First record for the municipio and central Sonora, extending the range 128 airline km WNW of Yécora, Municipio de Yécora (Rorabaugh et al. 2008. J. Arizona-Nevada Acad. Sci. 40:20–65), and lowers the elevational range in Sonora by 436 m (review of museum records in Madrean Archipelago Assessment database, Madrean.org). The snake was diurnally active in a flat area in the bottom of a bajío (arroyo) surrounded by foothills thornscrub.

THOMAS R. VAN DEVENDER, Sky Island Alliance, P.O. Box 41165, Tucson, Arizona 85717, USA (e-mail: vandevender@skyislandalliance.org); **EDUARDO GÓMEZ-LIMÓN**, Comisión Nacional de Áreas Naturales Protegidas, Av. ***LAMPROPELTIS NIGRA* (Eastern Black Kingsnake)**. USA: MISSOURI: Scott Co.: General Watkins Conservation Area, 2.34 km NNE Morley (37.064075°N, 89.604495°W; WGS84). 21 May 2011. Brian S. Edmond and Richard E. Daniel. Verified by Katy E. Klymus (confirmed using mtDNA). University of Missouri-Columbia (UMC 2038P color photograph). First documented record for this species in the state of Missouri (Daniel and Edmond 2014. Atlas of Missouri Amphibians and Reptiles for 2013 <http://atlas.moherp.org/pubs/atlas13.pdf> Updated 30 January 2014.) Adult female found among riprap in fishing lake #3 spillway.

Collection on state land authorized by Missouri Department of Conservation Wildlife Collectors Permit 14853.

RICHARD E. DANIEL, Division of Biological Sciences, University of Missouri, Columbia, Missouri 65211, USA (e-mail: danielr@missouri.edu); **BRIAN S. EDMOND**, Computer Services, Missouri State University, Springfield, Missouri 65897, USA (e-mail: BrianEdmond@missouristate.edu).

***LAMPROPELTIS NIGRA* (Eastern Black Kingsnake)**. USA: TENNESSEE: Williamson Co.: 100 Farrier Lane, Franklin (35.93121°N, 86.876061°W; WSG 84). 12 May 2014. Brittany Cromwell and Nicole Foster. Verified by A. Floyd Scott. Austin Peay State University (APSU 19492). New county record (Scottand Redmond

2008 [latest update: 10 March 2014]. Atlas of Reptiles in Tennessee. The Center for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/, accessed 14 May 2014).

BRITTANY CROMWELL (e-mail: bcromwell2@Columbiastate.edu) and **NICOLE FOSTER**, Department of Biology, Columbia State Community College, Columbia, Tennessee 38401, USA (e-mail: nfoster2@Columbiastate.edu).

***LAMPROPELTIS TRIANGULUM* (Milksnake)**. USA: TEXAS: Callahan Co.: Hwy 283 ca. 16 mi. N of Coleman, only a few meters north of the Callahan-Coleman Co. line (32.14°N, 99.42°W; WGS 84). Christian L. Cox. Verified by Toby J. Hibbitts. University of Texas at Arlington Amphibian and Reptile Diversity Research Center Collection (UTA DC 8135). New county record (Dixon 2013. Amphibians and Reptiles of Texas with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. 3rd ed., Texas A&M University Press, College Station, Texas. 447 pp.). Found under a rock on a roadside hill.

CHRISTIAN L. COX, The University of Virginia, Department of Biology, 485 McCormick Rd., Charlottesville, Virginia 22904, USA (e-mail: clcox@virginia.edu); **COREY E. ROELKE**, The University of Texas at Arlington, Department of Biology, Box 19498, Arlington, Texas 76019, USA (e-mail: croelke@uta.edu).

***LEPTODEIRA SEPTENTRIONALIS* (Cat-eyed Snake)**. USA: TEXAS: Kleberg Co.: ~ 120 m NE jct of TX FM 771 and Kleberg Co. Rd. 1100 (27.2978°N, 97.7576°W; WGS 84). 12 January 2014. Tawni Osborne and Charles Strubhart. Verified by Carl J. Franklin. University of Texas Arlington Digital Collection (UTA-DC 8109). New county record (Dixon 2013. Amphibians and Reptiles of Texas with Keys, Taxonomic Synopses, Bibliography, and Distribution Maps. 3rd ed., Texas A&M University Press, College Station, Texas. 447 pp.)

This record confirms this species' presence in Kleberg Co. and extends the range northward along the Texas coastal plain ~ 10 km NE of Sarita, in northern Kenedy Co., where other specimens are known (R. L. Powell, pers. comm.). Dixon (2013, *op. cit.*) noted "an isolated museum record for Kleberg County is questionable." The referenced questionable record is MVZ 75963, a fluid-preserved DOR specimen collected by E. Turner "11 miles SW of Sarita via Hwy 77" on 16 April 1963. This location was recorded as Kleberg Co. in error, but is actually further south in Kenedy Co. (E. Turner, pers. comm., March 2014).

GK made an observation (previously undocumented) of this species crossing FM 771 ~ 5 km E of Riviera in Kleberg Co. shortly after Hurricane Celia in August 1970.

GERALD KEOWN (e-mail: keown@lepidus.net) and **GERARD T. SALMON** (e-mail: gerardtsalmon@gmail.com), Southwestern Center for Herpetological Research, PO Box 624, Seguin, Texas 78156, USA.

***MYRIOPHOLIS BOUETI* (Bouet's Worm Snake)**. REPUBLIC OF CAMEROON: NORTHERN PROVINCE: Kismatari (9.32°N 13.49°E, elev. 190 m), below a cotton plantation in a trap. 11 October 2013. Patrick Prudent. Verified by Jean-François Trape. MNHN 2013.1018. New country record. This Sudanian savanna snake species was previously known from Senegal, Mauritania, Gambia, Guinea-Bissau, Mali, and Burkina Faso with an eastern extension into Niger and western Chad (along the northeast Cameroonian border) (Trape and Mané 2006. Guide des serpents d'Afrique occidentale – savane et désert. IRD éditions, Paris. 226 pp.; Wallach et al. 2014. Snakes of the World, A Catalogue of Living and Extinct Species. CRC Press, Taylor & Francis Group, Boca Raton, London, New York. i–xxvii, 1209 pp.). The species has never been reported from Cameroon (Chirio and LeBreton 2007. Atlas des Reptiles du Cameroun. Muséum national d'Histoire naturelle, IRD, Paris [Patrimoines Naturels 67], 688 pp.). This specimen is likely part of the easternmost population of this species like those from Chad, which is separated from the western population by Nigeria from which the species has not been reported.

IVAN INEICH, Muséum national d'Histoire naturelle, ISYEB (Institut Systématique Biodiversité, Évolution) UMR 7205 CNRS/EPHE/MNHN/UPMC, 57 rue Cuvier (CP 30), 75231 Paris cedex, France (ineich@mnhn.fr); **PATRICK PRUDENT**, CIRAD/IRAD, B.P. 1146, Garoua, Cameroun.

***PANTHEROPHIS EMORYI* (Great Plains Ratsnake)**. USA: COLORADO: Moffat Co.: 0.5 km S Ladore Ranger Station, Dinosaur National Monument (40.723168°N, 108.887675°W, WGS 84; elev. 1640 m). 6 June 2014. Timothy Warfel, Ian Jessup, Ryan Urbanek, Joshua Warfel, and Keian Velasquez. Verified by Lauren Livo. UCM Ancillary Collection (178-1 and 178-2, photo vouchers). New county record (Hammerson 1999. Amphibians and Reptiles in Colorado, 2nd ed. University Press of Colorado & Colorado Division of Wildlife, Niwot, Colorado. 484 pp.). An adult male *Pantherophis emoryi* was observed constricting a small rodent at the base of a rabbitbrush (*Chrysothamnus* sp.) next to the Green River. This record extends the known range of this species approximately 25 km NE in the Green River drainage from a record in Uintah Co., Utah (Bury 1983. Herpetol. Rev. 14[4]:123).

TIMOTHY WARFEL, 8326 W. Woodard Dr, Lakewood, Colorado 80227, USA; e-mail: tviridis@gmail.com.

***PITUOPHIS MELANOLEUCUS MELANOLEUCUS* (Northern Pinesnake)**. USA: TENNESSEE: Carroll Co.: Boyd's Landing Road at gate to Carroll County Recreation Lake (36.9354°N, 88.4612°W; NAD 84). 8 May 2014. John Maxwell, Jr. Verified by Chris Gienger. David H. Snyder Museum of Zoology, Austin Peay State University (APSU 19493). Adult male (total length ca. 153 cm) found DOR in mix of standing hardwoods. New county record (Scottand Redmond 2008 [latest update: 19 May 2014]. Atlas of Reptiles in Tennessee. The Center of Excellence for Field Biology, Austin Peay State University, Clarksville, Tennessee. Available at http://apsu.edu/reptatlas/,accessed 28 May 2014).

Voucher specimen collected under Tennessee Wildlife Resources Agency Scientific Collection Permit # 3690.

JOHN MAXWELL, JR., Bethel University, 325 Cherry Avenue, McKenzie, Tennessee 38201, USA (e-mail: jmaxwell07@bethelu.edu); **A. FLOYD SCOTT**, Department of Biology and Center of Excellence for Field Biology, Austin Peay State University, Clarksville, Tennessee, USA (e-mail: scotta@apsu.edu).

***REGINA ALLENI* (Striped Crayfish Snake)**. USA: FLORIDA: Baker Co.: Olustee, National Forest Rd 241(30.243512°N, 82.457107°W, WGS84; elev. 47 m). 6 June 2014. Noah J. Mueller and Shaun M. Duke. Verified by Kevin M. Enge. Florida Museum of Natural History (photographic voucher UF-Herpetology 173429). New county record (Krysko et al. 2011. Atlas of Amphibians and Reptiles in Florida. Final Report, Project Agreement 08013, Florida Fish and Wildlife Conservation Commission, Tallahassee, Florida. 524 pp.).

This snake was observed crossing a gravel road at dusk near Ocean Pond in Osceola National Forest. Our record represents the first from Baker Co. The next nearest known verified voucher from Florida is > 50 km in Alachua Co. (UF-Herpetology 1308). Although *Regina alleni* has been found in southern Georgia

(Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.), this find helps establish the range of *R. alleni* in north peninsular Florida.

***TANTILLA PLANICEPS* (Western Black-headed Snake)**. USA: CALIFORNIA: San Luis Obispo Co.: Caliente Mtns., Morales Canyon watershed, approx. 11.6 air mi. SSE Soda Lake (35.08189°N, 119.80571°W, WGS84; elev. 1305 m). 24 April 2011. C. J. Evelyn and L. C. Henry. Verified by Samuel S. Sweet. University of California-Santa Barbara, Vertebrate Museum collection 32732. New county record (museum records [UCSB, Cal Poly SLO, Herpnet.org]. Range maps (Californiaherps.com) drawn to include San Luis Obispo Co. are not based on museum or sight records (G. Nafis, pers. comm.). Nearest record is from Santa Barbara Co., Miranda Pine Mountain Road, 2.5 mi NW of Miranda Pine Mtn. (CAS 190348), 14 airline km to the E/SE. Adult female encountered under a juniper stump in open juniper woodland. Another individual was also seen at the surface but avoided capture.

CHRISTOPHER J. EVELYN, Department of Evolutionary and Marine Biology, University of California, Santa Barbara, California 93106, USA (e-mail: christopher.evelyn@lifesci.ucsb.edu); **LAURIE C. HENRY**, Oceanview Middle School, 4200 Olds Road, Oxnard, California 93033, USA (e-mail: lhenry@oceanviewsd.org).

***TROPIDODIPSAS FASCIATA* (Banded Snail-sucker)**. GUATEMALA: EL PETÉN: Laguna del Tigre National Park, Estación Biológica Las Guacamayas, Río Sacluc (17.233557°N, 90.283492°W; WGS84), 54 m elev. 30 May 2013. Rowland Griffin. Verified by Eric N. Smith. UVGF 0001. This represents the first record of *T. fasciata* in Guatemala (Wilson and Johnson 2010. *In* Wilson et al. [eds.], Conservation of Mesoamerican Amphibians and Reptiles, pp. 31–235, Eagle Mt. Publishing, Eagle Mt., Utah), and a range extension of ca. 170 km from 1.2 km E Ixbonil, Campeche Mexico (Lee 1996. The Amphibians and Reptiles of the Yucatán Peninsula. Comstock Publ. Assoc., Ithaca, New York. xii + 500 pp.; AMNH R-149561). The male snake was found in a swampy area interspersed by thorn scrub on the eastern bank of the Sacluc River. Our research was conducted under license from CONAP Resolución No.109-2013.

ROWLAND GRIFFIN, Project Chicchan, c/o Estación Biológica Las Guacamayas, Avenida 15 de Marzo, Flores, Petén, Guatemala (e-mail: rowland@project-chicchan.co.uk); **GARY POWELL**, Amphibian and Reptile Conservation Trust, 655A Christchurch Road, Boscombe, Bournemouth, Dorset, BH1 4AP, UK (e-mail: gary.powell@arc-trust.org).

***VIRGINIA VALERIAE* (Smooth Earthsnake)**. USA: GEORGIA: Coweta Co.: Private residence on Bartlett Drive in Sharpsburg (33.397476°N, 84.666830°W; WGS 84). 19 March 2013. Nathan Baker. Verified by Gregory D. Hartman. Gordon State College (GSC-064). New county record (Jensen et al. 2008. Amphibians and Reptiles of Georgia. University of Georgia Press, Athens, Georgia. 575 pp.; J. Jensen, pers. comm.). Species has been documented in four adjoining counties (Jensen et al. 2008, *op. cit.*). Found in leaf litter in residential area.

Specimen collected under a Georgia Department of Natural Resources Scientific Collections Permit (29-WBH-12-122).

MICHAEL J. BENDER, Gordon State College, 419 College Drive, Barnesville, Georgia 30204, USA; e-mail: mbender@gordonstate.edu.

ERRATA

Various county records reported by Duffus et al. (2014. Herpetol. Rev. 45: 88, 92, 94, 97) for *Apalone spinifera*, *Diadophis punctatus*, *Hemidactylus turcicus*, *Lithobates sphenocephalus*, and *Storeria dekayi*, and by Bender et al. (2014. Herpetol. Rev. 45: 86, 93) for *Agkistrodon contortrix*, *Notophthalmus viridescens*, and *Scincella lateralis* in Georgia were not new records but instead represent additional records from the reported counties. Records of *Graptemys geographica* and *Pseudemys concinna floridana* were reported erroneously in Duffus et al. (2014. Herpetol. Rev. 45:90) and do not represent county records or range extensions for either species.

MICHAEL J. BENDER (e-mail: mbender@gordonstate.edu), **GREGORY D. HARTMAN** (e-mail: ghartman@gordonstate.edu), and **AMANDA L. J. DUFFUS** (e-mail: aduffus@gordonstate.edu), Gordon State College, Barnesville, Georgia 30204, USA.

Noteworthy Distributional Records for the Herpetofauna of Oaxaca, México

Even though there have been several recent accounts on the geographic distribution of the Oaxacan herpetofauna (e.g., Casas-Andreu et al. 1996, 2004; Kohler 2008, 2011 [in part]; Canseco-Márquez and Gutiérrez-Mayén 2010 [in part]; Johnson et. al. 2010 [in part]; Wilson and Johnson 2010 [in part]), presumably many range gaps remain within the state. From 2011 through 2014, we began actively searching for amphibians and reptiles in Oaxaca to fill in those lapses, primarily in the central and southcentral portions of the state. Herein, we report new municipality records for four frogs, three lizards, and five snakes. All specimens were photographed *in situ* and released. Photographic vouchers were deposited in The University of Texas at El Paso Biodiversity Collections (UTEP) and Laboratorio de Herpetología, Facultad de Estudios Superiores, Universidad Nacional Autónoma de México (UNAM FES MCBFES). Taxonomy follows Wilson et al. (2013a, b) and Ruane et al. (2014) and common names are those listed in Liner and Casas-Andreu (2008). Map datum for coordinates was WGS84.

ANURA — FROGS

***CRAUGASTOR PYGMAEUS* (Pigmy Robber Frog).** Municipality of Santa Catarina Juquila: San Marcos Zacatepec (16.145209°N, 97.356447°W), 800 m elev. 21 June 2014. Eduardo Mata-Silva and Isabel Cortez-Cristobal. Verified by Luis Canseco-Márquez. UTEP G-2014.11. This record closes a gap in Oaxaca of ca. 106 km between 11.2 km S of Putla Villa de Guerrero (UTEP 7767–7769; www.herpnet.org, accessed 29 July 2014), in the Municipality of Putla Villa de Guerrero, and 16 km S of San Pedro Juchatengo, Municipality of San Juan Lachao (KU-H 86882, 86883; www.herpnet.org, accessed 29 July 2014). The specimen was found calling in a coffee plantation within remnants of cloud forest.

***DENDROPSOPHUS SARTORI* (Taylor's Yellow Treefrog).** Municipality of San Sebastián Ixcapa: San José Camotinchán (16.554222°N, 98.129144°W), 187 m elev. 20 June 2014. Vicente Mata Silva. Verified by Larry D. Wilson. UTEP G-2014.8. This record closes about a 13 km gap between 20 km ESE of Ometepec, Guerrero, and 9.3 km W of Puerto Escondido, Municipality of San Pedro Mixtepec, Oaxaca (Duellman 2001). The male was found calling in vegetation at the edge of a pond.

***ELEUTHERODACTYLUS NITIDUS* (Shiny Peeping Frog).** Municipality of Santa Catarina Lachatao: Santa Catarina Lachatao (17.264167°N, 96.486944°W), 2100 m elev. 25 August 2013. Haydée Morales Flores and Elí García-Padilla. Verified by Luis Canseco-Márquez. UTEP G-2013.3. This site is ca. 27 km NE from the nearest reported locality, 2 km S of San Mateo Huayapan, Municipality of Tlalixtac de Cabrera (IBUNAM-CNAR-AR 1858; www.herpnet.org, accessed 9 October 2013). However, we were unable to locate any town named San Mateo Huaypan; therefore the distance was an estimate. The specimen was found under a rock in pine-oak forest.

**Corresponding author*

***LITHOBATES SPECTABILIS* (Showy Leopard Frog).** Municipality of San Pedro Totolapan: Rancho El Jabalín (16.743056°N, 96.313333°W), 1674 m elev. 26 June 2011. Elí García-Padilla. Verified by Luis Canseco-Márquez. UTEP G-2013.4. The location is ca. 35 km E from the closest reported record near Praxedis de Guerrero, Municipality of Ocotlán de Morelos (IBUNAM-CNAR-AR 9048; www.herpnet.org, accessed 9 October 2013). The specimen was found in a pond surrounded by oak forest.

SQUAMATA — LIZARDS

***MARISORA BRACHYPODA* (Central American Mabuya).** Municipality of San Pedro Totolapan: Rancho El Jabalín (16.742778°N, 96.313611°W), 1670 m elev. 26 June 2011. Elí García-Padilla. Verified by Aurelio Ramírez-Bautista. UTEP G-2013.5. The locality is ca. 41 km N of the nearest reported locality at San José Lachiguiri, Municipality of San José Lachiguiri (UCM-Herps-41138; www.herpnet.org, accessed 9 October 2013). The lizard was found active on the ground in oak forest.

***MESASPIS JUAREZI* (Sierra de Juárez Alligator Lizard).** Municipality of Santa Catarina Ixtepeji: La Cumbre Ixtepeji (17.193333°N, 96.639722°W), 2910 m elev. 9 June 2012. Haydée Morales Flores and Elí García-Padilla. Verified by Luis Canseco-Márquez. UTEP G-2013.6. The locality is ca. 31 km SSW from the nearest record, ca. 16.1 km SE Llano de las Flores, presumably in the Municipality of Calpulalpam de Méndez (no coordinates are given) (Karges and Wright 1987). The specimen was found under a rock in pine forest.

***XENOSAURUS PHALAROANTHEREON* (Chin-spotted Knob-scaled Lizard).** Municipality of San Pedro Totolapan: Rancho El Jabalín (16.742889°N 96.313653°W), 1670 m elev. 26 June 2011. Elí García-Padilla. Verified by Luis-Canseco-Márquez. UTEP G-2013.8. This record is located ca. 66 km NNW from the nearest reported locality, ca. 4 km NE of San Juan Acaltepec, Municipality of Santa María Ecatepec (Nieto-Montes de Oca et al. 2001). This species had been previously reported only in floristic-faunistic area 7 (Sierra Madre del Sur) of Oaxaca (Casas-Andreu, *et al.* 2004); the specimen reported here is from area 4 (Valles Centrales). The specimen was observed in oak forest.

SQUAMATA — SNAKES

***LAMPROPELTIS ABNORMA* (Guatemalan Milksnake).** Municipality of San Bartolo Coyotepec: Reyes Mantecón, Paraje Ojo de Agua (16.903789°N, 96.711072°W), 1586 m elev. 6 June 2014. Elí García-Padilla and Haydée Morales-Flores. Verified by Larry D. Wilson. UTEP G-2014.9. The record is ca. 30 km WSW from the closest previously reported locality ca. 3.2 km (2 mi.) NE of Tlacolula, in the municipality of the same name (MSB-Herps-22795; www.herpnet.org, accessed 22 July 2014). The snake was found dead on a dirt road along an arroyo surrounded by secondary growth of tropical deciduous forest.

***OPHRYACUS UNDULATUS* (Mexican Horned Pitviper).** Municipality of Santa Catarina Lachatao: Santa Catarina Lachatao (17.265939°N, 96.491211°W), 1919 m elev. 21 July 2012. Haydée Morales-Flores and Elí García-Padilla. Verified by Luis Canseco-Márquez. UNAM FES MCBFESI- 279. The record is ca. 27 km NW from the closest previously reported locality on Cerro San Felipe, near Oaxaca City (Lynch and Smith 1966). The snake was found alive on a dirt road along a river, in an ecotone between tropical deciduous forest and pine-oak forest.

***PORTHIDIUM DUNNI* (Dunn's Hog-nosed Pitviper).** Municipality of Santa María Huatulco: on road to Playa San Agustín (15.683611°N, 96.265556°W), 128 m elev. 22 December 2012. Haydée Morales-Flores and Elí García-Padilla. Verified by Luis Canseco-Márquez. UTEP G-2013.8. This record fills a distributional gap in Oaxaca between ca. 24 km W of the vicinity of Puerto Angel (USNM-VZAR-30267) and ca. 100 km NNE of a location 83 km (52 mi.) W of Tehuantepec on Mexico Hwy 190 (UCM-Herps-19051; www.herpnet.org, accessed 9 October 2013). The specimen was found dead on a dirt road surrounded by tropical deciduous forest.

***STENORRHINA FREMINVILLII* (Freminville's Scorpion-eating Snake).** Municipality of Oaxaca de Juárez: Agencia de San Luis Beltrán (17.094722°N, 96.689167°W), 1627 m elev. 27 June 2013. Haydée Morales-Flores and Elí García-Padilla. Verified by Aurelio Ramírez-Bautista. UTEP G-2013.9. This record is from ca. 62 km NW from the closest reported locality in San Pedro Totolapan (Smith and Taylor 1945). Municipality of San Lorenzo de Albarradas: Hierve El Agua (16.864285°N, 96.276261°W), 1681 m elev. 18 December 2013. Eduardo Mata-Silva, and Isabel Cortez-Cristobal. Verified by Jerry D. Johnson. UTEP G-2014.11. This record is from ca. 22 km N of the San Pedro Totolapan record; the snake was found in thorn wood land.

***THAMNOPHIS LINERI* (Liner's Gartersnake).** Municipality of Santa Catarina Ixtepeji: Las Cabañas (17.193472°N, 96.639842°W), 2908 m elev. 9 June 2012. Haydée Morales-Flores and Elí García-Padilla. Verified by Douglas A. Rossman. UTEP G-2013.10. This record is from ca. 31 km SSW from the type locality in Llano de las Flores, Municipality of San Juan Atepec (Rossman and Burbrink 2005).

Acknowledgments.—Special thanks to Haydée Morales-Flores, Azul Haydée Gijón-Morales, K´in B´alam García-Morales, Eduardo Mata-Silva, and Isabel Cortez-Cristobal, who kindly provided help and company during the field expeditions, and to Arthur H. Harris and Alejandro Calzada-Arciniega, who kindly provided photo voucher numbers. We also want to thank Expediciones Lachatao and the community of Santa Catarina Lachatao, for allowing us to search for the herpetofauna within their well-maintained communal territory.

NATURAL HISTORY NOTES

GYMNOPHIONA — CAECILIANS

***GYMNOPIS MULTIPLICATA* (Varagua Caecilian). BIRTH.** *Gymnopis multiplicata* is a viviparous caecilian that provides post-birth maternal attendance to newborns (McCranie and Wake 2010. Herpetol. Rev. 41:483), which number 2–10 per clutch (Wake 1988. Cat. Amer. Amphib. Rept. 411.1–411.2). At 1715 h on 07 April 2012, we collected an adult female *G. multiplicata* (MVZ 269228, SVL = 328 mm, 115 primary annuli, 92 secondary annuli) and two neonate *G. multiplicata* (MVZ 269229, SVL = 107 mm, 120 primary annuli, 102 secondary annuli; MVZ 269230, SVL = 109 mm, 117 primary annuli, 98 secondary annuli) under a small wooden plank in the backyard of Hotel Río Indio Lodge, Departamento Río San Juan, Nicaragua (10.9303°N, 83.7272°W, datum WGS 84; elev. 20 m). Upon turning the plank with a rake we observed the adult female lying alongside one of the neonates and in the process of giving birth to a second neonate, which was approximately halfway out. Immediately after being exposed, the adult female tried to escape by quickly crawling away and was collected and deposited in a plastic bag. The birth of the second newborn was completed within three to five minutes, and we kept all three specimens together in a plastic bag partially filled with soil for approximately sixteen hours before preservation. No additional young were born. While examining the preserved specimens in the lab, M. H. Wake noticed that the adult female had one more intraoviductal fetus of approximately the same size as the other two newborns. The first two hatchlings came from the female's right oviduct, which was fully evacuated, and the remaining fetus was in the left oviduct. Assuming that these three fetuses constituted the whole clutch, it appears that the adult female *G. multiplicata* emptied one oviduct entirely before the other. Although the Río San Juan is one of the rainiest places in Central America and is included within Lowland Wet Forest formation, this field observation was made during the driest period of the year. This observation occurred on a day with overcast skies, but no rain, and the soil under the plank was relatively dry. No obvious food items were present.

CAUDATA — SALAMANDERS

***ANEIDES AENEUS* (Green Salamander). DEATH FEIGNING/IMMOBILITY.** The evolution of anti-predatory behaviors is an important component of the natural history of plethodontid salamanders. At 1325 h on 15 April 2013 in Powell Co., Kentucky, USA (37.816944°N, 83.680496°W, datum WGS84; elev. 381 m), we observed an adult *Aneides aeneus* (SVL = 5.5 cm) display immobility shortly after capture in a behavior we interpret as death feigning. The animal was gently coaxed from a cliff crevice using a small twig and quickly captured upon egress. Once in hand, within 15 seconds of capture, the animal flipped onto its back and lay limp for over three minutes. After about one minute, the animal gaped its mouth and assumed a more rigid posture. Once returned to the cliff, the animal quickly retreated into a fissure.

Anti-predatory behaviors such as immobility in response to physical contact and flipping onto the back have been reported for hatchling *Aneides* (Brodie et al. 1974. Herpetologica 30:79–85), but to our knowledge this is the first reported instance of death feigning or immobility upon contact in an adult *Aneides*. This genus is highly adapted to an arboreal existence and a primary mode of defense against predators is to wedge the body tightly into cracks and crevices (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Inst. Press, Washington, D.C. 587 pp.). Our observations suggest that death feigning may offer a second line of defense to *Aneides* if animals are extracted from their hiding places by a predator. The behavior we observed resembles Unken reflex but it differs in the strict sense because the ventral surface of *Aneides* is not brightly colored.

PRICE**, Department of Forestry, University of Kentucky, 214 Thomas Poe Cooper Building, Lexington, Kentucky 40546-0073, USA (e-mail: steven.price@uky.edu); **ANDREA N. DRAYER** (e-mail: andrea.drayer@uky.edu).

***CRYPTOBRANCHUS ALLEGANIENSIS* (Hellbender). PREDATION.** Predation on all life stages of *Cryptobranchus alleganiensis* by *Lontra canadensis* (River Otter) has been assumed, but evidence of predation has not been published (Briggler et al. 2007. Hellbender Population and Habitat Viability Assessment. IUCN/SSC Conservation Breeding Specialist Group, Apple Valley, Minnesota. 46 pp.). *Lontra canadensis* was presumably common in many *C. alleganiensis* localities, but was largely extirpated in many sites by the early 1900s due to the fur trade. River Otters have been reestablished through reintroduction efforts in many parts of the eastern USA. The effects of reintroductions on *C. alleganiensis* has been of concern due to potential for predation, disease introductions, and food competition (Nickerson et al. 2011. PLoS ONE 6:e28906). On 23 October 2013, one of us (RV) was traveling westbound on State Rt. 73 along the East Prong of Little River in the Tennessee portion of Great Smoky Mountains National Park (precise locality withheld due to conservation concerns). At 1230 h, RV pulled over to observe three *L. canadensis* in the river and photographed the predation of an adult *C. alleganiensis* by an adult *L. canadensis* for approximately four minutes. The *L. canadensis* was originally near the north river bank with the tail of the *C. alleganiensis* in its mouth. The *L. canadensis* carried the *C. alleganiensis* to the middle of the river and climbed on to a large rock where it began to consume it beginning at the tail. The *L. canadensis* went back into the water and climbed onto a second rock further upstream, where it continued feeding on the *C. alleganiensis* (Fig. 1). It stayed there briefly before reentering the river, with the *C. alleganiensis* still in its mouth, and continued upstream until no longer in view. At that time the back portion of the *C. alleganiensis*, including the entire tail, rear legs, and part of the rear body cavity, was mostly consumed. The two other *L. canadensis* were further upstream during the observation. Due to the appearance of the body and skin of the *C. alleganiensis* and changes in the position of the *C. alleganiensis* in photographs, it seems likely that it was alive during the predation event.

We thank Erik Cooper, Tiffany Beachy, and Dana Soehn for providing information about this event.

FIG. 1. Adult *Lontra canadensis* (River Otter) feeding on an adult *Cryptobranchus alleganiensis* (Hellbender) in Little River, Tennessee.

***CRYPTOBRANCHUS ALLEGANIENSIS ALLEGANIENSIS* (Eastern Hellbender). INTRASPECIFIC AGGRESSIVE BEHAVIOR.** Males of *Cryptobranchus alleganiensis* are known for their aggressive behaviors during the breeding season, especially defending nesting sites (Bishop 1941. The Salamanders of New York. New York State Museum Bulletin. No. 324. Albany, New York. 365 pp.; Nickerson and Mays 1973. The Hellbenders: North American Giant Salamanders. Milwaukee Public Museum, Milwaukee, Wisconsin. 106 pp.; Smith 1907. Biol. Bull. 13:5–39). Such male-to-male intraspecific aggression sometimes inflicts considerable injury to an opponent; resulting in scrapes, gashes, fresh wounds to the limbs, head, flank or tail, and most injuries are likely associated with the breeding season (Hiler et al. 2005. J. Arkansas Acad. Sci. 59:88–94; Miller and Miller 2005. Southeast. Nat. 4:513–520; Pfingston 1990. Herpetol. Rev. 21:48–51). Herein we report two observations of aggressive behavior during the breeding season in male hellbenders, and one of these observations resulted in mortality of a conspecific. To our knowledge, this is the first reported observation resulting in mortality.

While conducting surveys for hellbender nests at 1115 h on 02 October 2008 on the Big Piney River, Missouri, USA (specific locality withheld due to conservation concerns), we encountered a large amount of hellbender slime scattered on the river bottom within an approximately 3 x 3 m area. A hellbender was seen lying within this area on the river bottom with its head poked into a hole under a large rock (mean rock length and width 130 and 210 cm, respectively). Upon grabbing and removing the hellbender from the hole, we observed that another hellbender had its mouth engulfed over the nostrils and half of the head. The hellbender within the hole immediately released the other hellbender and retreated slightly backward within the hole of the large rock. The hellbender that was captured was covered with large amounts of whitish skin secretions, was only slightly active, and was immediately placed in a container with water for short-term observation. The hellbender was an adult male (SVL = 34.0 cm; total length = 46.0 cm; mass = 610 g) and died within 15 minutes of capture. We were unable to remove the adult that was under the rock, but it appeared to be larger in size (i.e., larger head) and was likely a male based upon its behavior of defending the entrance tunnel of a potential nesting site. Based upon copious amounts of whitish skin secretions on the river bottom, it appears that aggressive fighting had occurred in the general area of the rock, but what happened and the length of the fighting is unknown. The animal that died had two snout wounds resembling bite-marks and fresh lacerations on the front and back left limbs indicative of bite marks by another hellbender. Necropsy was performed on the dead body and nothing else unusual was found.

At 0900 h on 24 September 2013, another similar encounter occurred between two adult male hellbenders on the Gasconade River, Missouri, USA (specific locality withheld due to conservation concerns). We observed a hellbender (SVL = 31.2 cm; total length = 47.3 cm; mass = 515 g) with its tail and partial body lying parallel to a rock (mean rock length and width of 86 and 66 cm respectively) and its head under the rock. When the hellbender was grabbed and pulled from the rock, another hellbender (SVL = 29.6 cm; total length = 46.1 cm; mass = 535 g) was immediately removed with its jaws clasped over the upper jaw and head of the visible hellbender. The hellbender released the other and both were alive and in good body condition. Upon inspection of the body, both hellbenders had characteristic snout wounds resembling bite-marks on the head.

Although eggs were not observed during either of these encounters, fierce fighting among male hellbenders during competition for good nesting sites is known to occur (Alexander 1927. Buffalo Soc. Nat. Sci. 7:13–18; Nickerson and Mays 1973, *op. cit.*; Peterson 1988. Herpetol. Rev. 19:28–29). In both of these incidences we report, the males within the holes of these rocks were likely defending nesting sites. The only other documentation with similar aggression was reported in Nickerson and Mays (1973, *op. cit.*) where an incident of strife occurred on the open river bottom between two adult Ozark Hellbenders (*C. a. bishopi*), but no mention of death was reported. Such intraspecific male-to-male aggression, especially during the breeding season, may be somewhat common in *C. a. alleganiensis*, but those resulting in death are likely a rare occurrence.

This work was funded by the Missouri Department of Conservation and Fort Leonard Wood. We thank the numerous staff of various agencies that assisted with field surveys. Research was conducted in compliance with applicable animal care guidelines and appropriate permits were obtained.

***CRYPTOBRANCHUS ALLEGANIENSIS BISHOPI* (Ozark Hellbender). DIET.** The diet of *Cryptobranchus alleganiensis* consists predominantly of crayfish; small fishes (e.g., catostomids, cyprinids, and cottids) are the most common vertebrates in their diet (Nickerson and Mays 1973. The Hellbenders: North American Giant Salamanders. Milwaukee Public Museum, Milwaukee, Wisconsin. 106 pp.). A variety of other foods have also been reported: invertebrates include earthworms, aquatic insect larvae, insects, and snails; while vertebrate prey includes fish eggs, lampreys, hellbender eggs and conspecifics, tadpoles, toads, snakes and small mammals (Groves and Williams 2013. Herpetol. Rev. 44:651–652; Hulse et al. 2001. Amphibians and Reptiles of Pennsylvania and the Northeast. Cornell University Press, Ithaca, New York. 419 pp.; Nickerson and Mays 1973, *op. cit.*; Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 587 pp.; Smith 1907. Biol. Bull. 13:5–39). Hulse et al. (2001, *op. cit.*) reported *Cryptobranchus a. alleganiensis* (Eastern Hellbender) occasionally eats *Necturus maculosus maculosus* (Common Mudpuppy). *Necturus m. louisianensis* (Red River Mudpuppy) occurs syntopically with the regionally endemic *Cryptobranchus a. bishopi* (Ozark Hellbender) in rivers of the southern Ozark Plateau of Arkansas and Missouri, and mudpuppies are frequently encountered during hellbender monitoring work. We report here the first recorded instance of an Ozark Hellbender feeding on the Red River Mudpuppy.

While checking a series of artificial nest boxes for the presence of egg clutches on 23 October 2012 in the Eleven Point River, Randolph Co., Arkansas, USA (precise locality data withheld due to federal endangered species status of the Ozark Hellbender), four adult male Ozark Hellbenders were collected within adjacent habitat. All four of these individuals had been previously captured and PIT tagged as part of an ongoing long-term population monitoring project (KJI). One of these males (SVL = 29.5 cm; total length = 45.7 cm; mass = 497 g) was initially captured in 2007, and while temporarily housed in a plastic storage tub it regurgitated an adult *N. m. louisianensis* (ASUMZ 33029; SVL = 18.0 cm; total length = 25.0 cm; mass = 83 g; Fig. 1). The mass of the *Necturus* represents 16.7% of the body weight of the *Cryptobranchus*. The *Necturus* exhibits significant tissue damage along the midline of the dorsum, with some separation of the musculature along the axial plane of the vertebral column, in what appears to be two distinct bite marks. The venter lacks any discernable tissue damage. The orientation of the bite marks suggests that the *Cryptobranchus* approached and grabbed the *Necturus* from the lateral aspect. In over a decade of field work, and many hundreds of *Cryptobranchus* captures, this is the first instance that we have observed predation of *Necturus* by *Cryptobranchus*.

***DESMOGNATHUS FOLKERTSI* (Dwarf Black-bellied Salamander). PREDATION.** *Desmognathus folkertsi* is a recently described species (Camp et al. 2002. Herpetologica 58:471484), and predators have not been previously documented. On 01 July 2010 at approximately 1030 h we discovered a subadult *D. folkertsi* as it was being eaten by a juvenile *Nerodia sipedon* (Northern Watersnake). The location was a small, 1st order stream in Habersham Co., Georgia, USA (34.66840°N, 83.36798°W; datum WGS 84). The watersnake had seized the center of the body of the salamander, which writhed and bit, including biting its own leg (Fig. 1). The salamander was re-growing a previously lost tail, possibly indicating that it had survived an earlier predatory attack. Tail autotomy is an anti-predatory behavior characteristic of many salamanders including *Desmognathus* (Labanick 1984. Herpetologica 40:110–118). Although this is a first record of predation

FIG. 1. *Nerodia sipedon* feeding on a juvenile *Desmognathus folkertsi*.

upon *D. folkertsi*, several species of the genus *Nerodia* including *N. sipedon* are known to eat desmognathine salamanders (Gibbons and Dorcas 2004. North American Watersnakes: A Natural History. University of Oklahoma Press, Norman. 438 pp.).

SPEAR**, and **DIRK J. STEVENSON**, Project Orianne, Clayton, Georgia 30525, USA; **CARLOS D. CAMP**, Department of Biology, Piedmont College, Demorest, Georgia 30535, USA (e-mail: ccamp@piedmont.edu).

***EURYCEA CIRRIGERA* (Southern Two-lined Salamander). PAEDOMORPHOSIS.** On 19 January 2014, we discovered what appeared to be a large (SVL = 38 mm; total length = 75 mm), but typically marked, *E. cirrigera* larva in a small, impounded stream in Athens, Clarke Co., Georgia, USA (33.8909°N, 83.3624°W; datum: WGS84). However, the larva was visibly gravid; developing ova could be seen through her transparent ventral skin. The salamander was euthanized and dissected and found to have 27 distinct ova in her right oviduct and 24 ova in her left oviduct. This falls within the typical clutch size of the species (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, DC. 587 pp.). Tissues from the female and her eggs were preserved in 95% EtOH, and deposited as GMNH 50696. To the best of our knowledge, the only other report of neoteny in *E. cirrigera* was from Mount (1975. The Amphibians and Reptiles of Alabama. University of Alabama Press. 268 pp.), who described it as "not uncommon" in Alabama. Rose and Bush (1963. Tulane Stud. Zool. 10:121–128) describe several male and female *E. aquatica* with well-developed testes and ova, but report that all had typical adult coloration and classify their status as representative of "precocious reproductive development and not true neoteny". No other published accounts of neoteny in the *Eurycea bislineata* complex exist. We revisited the site of collection and nearby streams on 26 January 2014 and collected 53 *E. cirrigera* larvae, but all were smaller than the gravid female and none had visible developing ova. Metamorphosed adult female *E. cirrigera* were gravid during this time. Additionally, we examined 74 *E. cirrigera* larvae of at least 30 mm SVL in the GMNH collection, and none of them appeared to be gravid females.

KIRA McENTIRE, TODD W. PIERSON (e-mail: twpierso@uga.edu), and **JOHN C. MAERZ,** Warnell School of Forestry and Natural Resources, University of Georgia, Athens, Georgia 30602, USA.

***EURYCEA TYNERENSIS* (Oklahoma Salamander). TERRESTRIAL OVIPOSITION.** *Eurycea tynerensis* is a plethodontid that inhabits streams of the Ozark Plateau in Oklahoma, Arkansas, and Missouri, USA. This is one of a few species of plethodontids that exhibit alternative life histories, including paedomorphosis and metamorphosis among populations, with some populations displaying both life histories (Bonett and Chippindale 2004. Mol. Eco. 13:1189–1203). Very little is known about the reproductive biology of paedomorphic *E. tynerensis*, and to date, paedomorphic *E. tynerensis* egg clutches have only been observed once in the wild (Trauth et al. 1990. Proc. Arkansas Acad. Sci. 44:107–113). Lack of observations is likely due to their aquatic lifestyle and affiliation with subterranean strata. Therefore, captive specimens may offer the best opportunity to document novel reproductive behaviors. Here we report multiple instances in captivity of a paedomorphic *E. tynerensis* depositing eggs above the waterline.

Our first observation took place in 2012, however no data was recorded. On 24 September 2013, another captive paedomorphic female *E. tynerensis* deposited four eggs on the inside edge of a large cattle tank above the water line. The female believed to have laid these eggs deposited a total of 15 eggs (on both terrestrial and aquatic surfaces), but oviposition was never witnessed. The presumed mother was also observed above the water line. On 12–13 October 2013, terrestrial oviposition by multiple female *E. tynerensis* from the same locality was observed, with a total of 30 eggs being deposited above the waterline and 31 deposited within water. Distance of the eggs from the waterline ranged from 2–16 cm (mean = 6.78 cm). The same captive facility houses seven additional populations of paedomorphic *E. tynerensis* (raised in a similar manner), none of which have exhibited terrestrial oviposition, even though over 20 clutches of eggs have been deposited.

Most *Eurycea* are known to deposit eggs in clutches on the undersides of submerged rocks or other debris in streams (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, DC. 587 pp.). Terrestrial oviposition in *E. tynerensis* appears to be a grave event and eggs that are not transferred into water quickly became desiccated. However, given that this behavior was observed multiple times from at least three individuals, terrestrial oviposition may

PHOTOGRAPH BY T. W. PIERSON

FIG. 1. Dorsal and ventral view of paedomorphic female *Eurycea cirrigera*.

be a recurring phenomenon in certain populations. Additional field observations are needed to determine the adaptive significance, if any, of this phenomenon.

MICHAEL A. STEFFEN (e-mail: michael-steffen@utulsa.edu), **JOHN G. PHILLIPS** (e-mail: john-phillips@utulsa.edu), and **RONALD M. BONETT,** University of Tulsa, Department of Biological Science, Tulsa, Oklahoma 74104, USA (e-mail: ron-bonett@utulsa.edu).

***NECTURUS MACULOSUS* (Common Mudpuppy). LARVAL GUARDING.** Larval defense and attendance of eggs and young by adults is a widespread behavior among salamanders (Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, D.C. 587 pp.). During salamander surveys in the Licking River watershed, Rowan Co., Kentucky, USA (precise locality withheld due to conservation conerns), we observed two separate instances of adult *N. maculosus* attending broods of larvae at different stages of development between 1045 h and 1150 h on 11 September 2013. Both aggregations were found by lifting large flat rocks in a stream approximately one meter in depth. The first adult *N. maculosus* (22 cm SVL) was in attendance of at least 32 larvae ranging from 4–5 cm in total length and the second adult *N. maculosus* (19 cm SVL) was in attendance of at least 25 larvae approximately 3–4 cm in total length. When initially uncovered, both females were coiled around a tightly aggregated group of larvae at the center of the space under the cover rock. Remnants of hatched eggs were evident on the underside of the rock concealing the smaller larvae, but were not detected under the other rock.

Adult *Necturus* have been reported to attend and guard clutches of eggs on the undersides of submerged flat rocks through hatching (Bishop 1941. New York State Mus. Bull. 324:13–65), but to our knowledge this is the first reported instance of larval attending in this species. We feel confident in describing these observations as larval attending rather than recently hatched nest guarding behavior because Bishop (1941, *op. cit.*) described *Necturus* hatchlings as measuring between 2.1–2.5 cm total length and our observed larvae were larger at approximately 3–5 cm total length. Breeding season and date of oviposition vary across the range of *N. maculosus*. Because larvae were found in September in this part of the range, copulation in central Kentucky may occur in the spring and eggs may be deposited in early to mid- summer. Larval *Necturus* may face strong predation pressures from fish, crayfish, invertebrates, and conspecifics, and the expression of larval attendance phenotypes in this species may be more prevalent in portions of the range where egg hatching coincides with low water levels and higher predator densities.

DRAYER** (e-mail: andrea.drayer@uky.edu), **STEVEN J. PRICE** (e-mail: steven.price@uky.edu), Department of Forestry, University of Kentucky, 214 Thomas Poe Cooper Building, Lexington, Kentucky 40546-0073, USA.

***NOTOPHTHALMUS VIRIDESCENS* (Eastern Newt). SPERM MOTILITY.** Amphibian sperm have received considerable attention in recent years because of the possibility of conserving genetic information and the propagation of threatened taxa. However, our understanding of sperm physiology in amphibians is rather limited, even on sperm in taxa that have been investigated for the explicit purpose of understanding sperm physiology.

Sperm transport and activation in male *N. viridescens* were studied in detail by Hardy and Dent (1986a. J. Exp. Zool. 240:385–396; 1986b. J. Morphol. 190:259–270). They reported that sperm were immotile in the Wolffian ducts and motile in the periphery of the spermatophore cap (also confirmed in Ambystomatidae and other salamandrids; Russel et al. 1981. Tiss. Cell. 13:609–621; Zalisko et al. 1984. Copeia 1984:739–747). Thus, activation of newt sperm must take place during, or immediately preceding, spermatophore formation. Hardy and Dent (1986a, *op. cit.*) concluded exposure of the spermatophore to pond water (hypoosmotic shock) was the initiating factor for axoneme activation and that sperm motility alone did not account for sperm reaching the simple spermathecae in female *N. viridescens* because sperm in natural inseminations traveled as far as 5 mm in less than 2 minutes. This distance could not possibly be traversed by sperm activated by hypoosmotic shock (Hardy and Dent 1986a, *op. cit.*). Thus, another mechanism modulating sperm swimming speed (or degree of activation) must be present.

While testing hypotheses on the function of secretions from the sexual collecting ducts of *N. viridescens* (see Siegel et al. 2012. J. Herpetol. 46:136–144), we observed an interesting finding: sperm are motile in the Wolffian ducts of *N. viridescens*. This finding contradicts the previous findings of Hardy and Dent (1986a, *op. cit.*). We examined freshly excised sperm from the Wolffian ducts of ten male *N. viridescens* captured on 05 November 2011 from Crawford Co., Missouri (37.94774°N, 91.16793°W; WGS 84). Specimens were euthanized with a lethal dose of MS-222 before sperm excision. We can only conclude that the error by Hardy and Dent (1986a, *op. cit.*) was due to examining desiccated sperm at the periphery of their sperm preparations.

Sperm in the Wolffian ducts of *N. viridescens* are motile, at least during November, in specimens collected from Missouri. Interestingly, Hardy and Dent (1986a, *op. cit.*) also collected salamanders in November. Historic studies on other salamander taxa also noted motility of sperm from the Wolffian ducts; e.g., Smith (1907. Contr. Zool. Lab. Univ. Michigan 109:5–39) stated in reference to sperm from the Wolffian ducts of *Cryptobranchus allegheniensis*, "the spermatozoa were motile; the motion of the shaft is slow as compared with other forms, but that of the undulating membrane is rapid." Smith (1907, *op. cit.*) noted that sperm remained motile longer in seminal fluid mixed with water (4 h) than in water alone (15 min), indicating that pure water might actually have an inhibiting effect on sperm motility. Smith (1907, *op. cit.*) also noted that sperm were not motile from the Wolffian ducts outside of the mating season. Moreover, it has long been suggested that the male excurrent ducts are the sites for maturation of salamander sperm (McLaughlin and Humphries 1978. J. Morphol. 158:73–90; Matsuda 1986. Gam. Res. 14:209–214), and it appears that this maturation includes activation of the axoneme in *N. viridescens*. From a study on *Ambystoma texanum* (Russell et al. 1981, *op. cit.*), sperm activation apparently takes place in the distal portion of the Wolffian ducts, as whorls of motile sperm were described. Sperm were not active more proximally. Furthermore, it has also been proposed that secretory activity of the Wolffian duct epithelium may act to sustain sperm motility while stored (Zalisko and Larsen 1988. Scan. Micro. 2:1089–1095).

We thank the Missouri Department of Conservation for collecting permits for this natural history note (permit #14791).

SUPPLEMENTARY MATERIAL: For a video of sperm excised directly from the Wolffian ducts of *Notophthalmus viridescens*, contact D. Siegel (dsiegel@semo.edu). In the video, motility of the entire mass of sperm and many sperm tails is obvious.

GRIBBINS,** Department of Biology, Wittenberg University, Springfield, Ohio 45501, USA; **JUSTIN L. RHEUBERT** and **ROBERT D. ALDRIDGE,** Department of Biology, Saint Louis University, St. Louis, Missouri 63103, USA.

***NOTOPHTHALMUS VIRIDESCENS* (Eastern Newt). DIET.** *Notophthalmus viridescens* is a common aquatic salamander across the eastern United States, and they are known to play important roles as predators in freshwater ecosystems (Morin 1981. Science 212:1284–1286; Smith 2006. Oecologia 148:342–349). *Notophthalmus viridescens* is known to prey upon aquatic invertebrates, conspecific larvae, anuran tadpoles and eggs, and fish (Burton 1977. Copeia 1977:139–143; Petranka 1998. Salamanders of the United States and Canada. Smithsonian Institution Press, Washington, DC. 587 pp.). They may also be scavengers, as evidenced by a single report of cannibalism on dead conspecifics (Pitt et al. 2011. Herpetol. Rev. 42:258). Here I describe *N. viridescens* scavenging dead minnows.

On 08 and 15 April 2013, I observed a total of four *N. viridescens* eating, or attempting to eat, dead juvenile *Luxilus cornutus* (Common Shiner) minnows in the shallows of a large pond in Pennsylvania State Game Lands 176, Centre Co., Pennsylvania, USA (40.80200°N, 77.94300°W; datum WGS84). Three *N. viridescens* were seen repeatedly biting floating *L. cornutus* (approximately 5 cm total length), a very common fish in this pond. One *L. cornutus* was also being grasped by a backswimmer (*Notonecta* sp.), which caused the corpse to move periodically as it swam. It did not appear that any flesh was removed when any of these *N. viridescens* bit the dead *L. cornutus*. A fourth, female *N. viridescens* was seen with the posterior half of a *L. cornutus* protruding from its mouth. It was captured with a net but immediately regurgitated the fish. It is doubtful that it could have successfully swallowed the entire *L. cornutus*, and none of the other *N. viridescens* observed appeared to have successfully consumed any of the fish. Live *L. cornutus* that were smaller, and thus might be swallowed by *N. viridescens*, were abundant. These observations provide evidence that *N. viridescens* may also be important scavengers of small fish, in addition to their role as predators, in lentic habitats.

I thank Jay Stauffer and his lab for identifying the minnow species. Funding was provided by the National Science Foundation (award #1311451 to T. Langkilde and B. E. Carlson) and the research was approved by Penn State University IACUC (#41757).

***PARAMESOTRITON LONGLIENSIS* (Longli Warty Newt). DEFENSIVE BEHAVIOR.** Salamanders and newts are well known to show defensive posture against a predator. Usually they roll up the ventral sides of body and tail to show the bright coloration (Duellman and Trueb 1986. Biology of Amphibians. The Johns Hopkins University Press, Baltimore. 670 pp.). Here we report a defensive behavior of *Paramesotriton longliensis* (Longli Warty Newt). At 2050 h on 30 March 2011, we found an adult female of *P. longliensis* (mass = 15.2 g) in a stream (depth ca. 1.2 m, width ca. 15 m) at Muye, Youyang County, Chongqing Municipality, China (29.27475°N, 109.00044°E; datum WGS84; elev. = 874 m). Water temperature was 15.0°C and air temperature was 11.0°C at capture. Immediately upon capture by a dip net, the newt laterally curved its body and coiled its tail, with its limbs folded and the coiled tail kept on the head (Fig. 1). A noxious smell emitted probably from body, but we could not observe any visible secretion. The newt did not move even in hand and also after kept in a plastic bag with water for more than several minutes. Similar behavior was also reported for other *Paramesotriton* sp. (Brodie 1983. *In* Margaris et al. [eds.], Plant, animal, and microbial

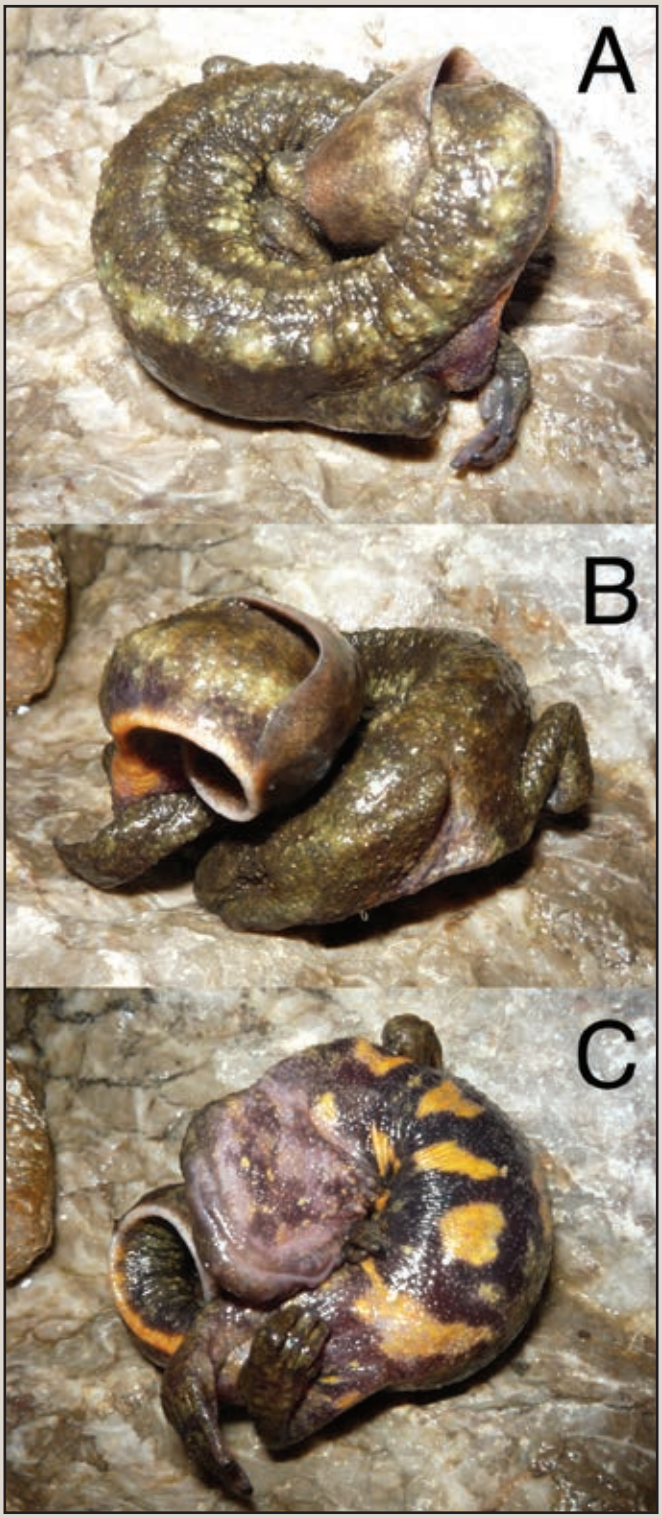

FIG. 1. Antipredator defense of a female *Paramesotriton longliensis*. A) Dorsal, B) lateral, C) ventral views.

adaptations to terrestrial environment, pp. 109–133. Plenum, New York), however, to our knowledge this is the first record of this behavior in this species.

KANTO NISHIKAWA, Graduate School of Human and Environmental Studies, Kyoto University, Yoshida Nihonmatsu-cho, Sakyo-ku, Kyoto 606-8501, Japan, and Chengdu Institute of Biology, Chinese Academy of Sciences, Chengdu 610041, China (e-mail: hynobius@zoo.zool.kyoto-u.ac.jp); **JIE WANG** (e-mail: wjie621@163.com), and **JIANPING JIANG**, Chengdu Institute of Biology, Chinese Academy of Sciences, Chengdu 610041, China (e-mail: jiangjp@cib.ac.cn).

***SALAMANDRA LONGIROSTRIS* (Prebetic Zone Fire Salamander). DIET.** Non-vertebrate prey are well known to be consumed by *Salamandra longirostris* (García-París et. al. 2004. *In* Ramos et al. [eds.], Fauna Iberíca, Vol. 24, p. 79. Museo Nacional de Ciencias Naturales, CSIC, Madrid, Spain), but vertebrate prey, to my knowledge, have never been reported. Two partially-digested *Pleurodeles waltl* (Spanish Ribbed Newt) larvae, each with a head width of approximately 4.2 mm, were found in the gut of a male *S. longirostris* (CM 54272) collected at 2030 h on 29 November 1970. The salamander was found dead but in otherwise good condition on roadway C-440 approximately 12 km SE of Casas del Castaño, Cádiz Province, Spain (36.21762°N, 5.57583°W, datum WGS84; elev. 107 m). Its total length in preservative is 196.5 mm. In addition to adding larval salamanders to the diet of adult male Fire Salamanders, at least in extreme southern Spain, this finding also suggests the species may actively forage in aquatic environments.

STEPHEN D. BUSACK, North Carolina State Museum of Natural Sciences, 11 West Jones Street, Raleigh, North Carolina 27601-1029, USA; e-mail: sbusack348@aol.com.

ANURA — FROGS

***COLOSTETHUS RUTHVENI* (Santa Marta Poison Arrow Frog). DIET.** *Colostethus ruthveni* is an endemic species found from the northwest flank of the Sierra Nevada de Santa Marta, Magdalena, Colombia; its distribution is estimated to be less than 5000 km^2. It resides along streams in cloud forests and dry tropical forests near the Caribbean coast (elev. <1540 m). It is considered endangered on the IUCN Red List of Threatened Species and its greatest threat is habitat loss and degradation due to agriculture, forest clearance, and infrastructure development (González-Maya et al. 2011. JoTT 3:1633–1636; Kaplan 1997. J. Herpetol. 31:369–375; Rueda-Solano and Castellanos-Barliza 2010. Acta. Biol. Col. 15:195–206). The food habits of this species are unknown, as well as many aspects of its ecology.

The study area has humid and wet tropical forests and is known as Bañaderos region and Camarones River's high basin. It is located in the south of the Riohacha municipality in La Guajira department. Sampling (approximately 165 person h effort) was conducted via visual encounter surveys carried out between 0700 h and 1800 h during 05–20 September 2011, in the basins of Camarones and Tapias rivers at three sites (11.0454°N, 72.5329°W; 11.0204°N, 72.5610°W; 11.0322°N, 72.5924°W; datum: D-Magna; elev. 408–710 m). The collected individuals were measured, preserved in ethanol, and dissected for the extraction of stomach contents. The prey was identified to order, family, and genus when possible, and the surface occupied by each prey type was measured using the coverage method (Tresierra and Culquichicon 1993. Manual de Biología Pesquera, pp. 47–56.Trujillo, Perú).

TABLE 1. Composition of prey in the diet of *Colostethus ruthveni* from Bañaderos region, Riohacha, Colombia.

Prey	Area mm^2 (%)	Frequency of occurrence
Arachnida		
Acari	0.5 (0.39)	1
Insecta		
Coleoptera		
Staphylinidae	6 (4.60)	1
Bruchidae	40 (30.8)	1
Curculionidae	4 (3.10)	1
Family Unknown	3 (2.30)	1
Hemiptera	0.5 (0.40)	1
Hymenoptera		
Formicidae		
Neivamyrmex sp.	11 (13.45)	9
Aphaenogaster sp.	11 (13.45)	9
Myrmicinae (Queen)	21 (16.2)	6
Solenopsis sp.	1.5 (1.20)	4
Larvae sp. 1	31 (23.8)	1

We examined 26 stomachs of *C. ruthveni* collected on the banks of streams inside the forest. 73.19% were found with stomach contents (N = 26; SVL = 1.9–2.31 cm, mean SVL ± S.D. = 2.09 ± 0.12 cm; Table 1). The diet consisted mainly of arthropods. Insects (Hymenoptera, Coleoptera, Hemiptera, and an unidentified larva) were the most important prey items (with more abundance and covered surface area), followed by scarce examples of arachnids (especially Acari). Coleopterans were the most important in surface coverage; however, it is worth noting that Bruchidae is represented by a single prey with large size consumed by a single *Colostethus ruthveni* individual. Numerically, the most important prey items were ants. Ants of the genus *Neivamyrmex* and *Aphaenogaster* occurred most frequently in the examined stomachs.

In Cordoba's region, in the north of Colombia, *Colostethus inguinalis* consumes beetles as the most important volumetric prey and ants as the most important numeric prey (Blanco-Torres et al. 2013. Herpetol. Rev. 44:493) which is totally consistent with *C. ruthveni*'s diet; however, the genus of Coleoptera and ants consumed differ between the two species. We also report the ingestion of mites (Acari) by *C. ruthveni*. Our contribution to the knowledge of the diet of *C. ruthveni* may be useful to management and conservation plans for this endemic species and its habitat.

***DENDROPSOPHUS PSEUDOMERIDIANUS* (Small Tree Frog). PREDATION.** There are reports of spiders preying on tadpoles (e.g., Luiz et al. 2013. Herpetol. Notes 6:451–452; Santos-Silva 2013. Herpetol. Notes 6:193–194), as well as some adults of the hylid genus *Dendropsophus* (e.g., Oliveira et al. 2010. Herpetol. Notes 3:299–300; Toledo 2005. Herpetol. Rev. 36:395–400). The frog *D. pseudomeridianus* occurs in lowlands of Rio de Janeiro and Espírito Santo states, southeastern Brazil. This species reproduces in marshes and deposits eggs on the surface of the water (Izecksohn and Carvalho-e-Silva 2010. Anfíbios do Município do Rio de Janeiro. UFRJ Press, Rio de Janeiro. 198 pp.). The tadpole of *D. pseudomeridianus* is nektonic, inhabits lentic water, and preys upon microorganisms (McDiarmid and Altig 1999. Tadpoles: The Biology of Anuran Larvae. Univ. Chicago Press, Illinois. 444 pp.). Wolf spiders (family Lycosidae) are usually ground-dwelling hunters and many species are diurnal. They use their relatively good vision and strong venom to capture and kill their prey. At 1930 h on 17 February 2014 in the Municipality of Guapimirim, state of Rio de Janeiro (22.35735°S, 42.571943°W; datum SAD69), we noted a young male wolf spider (*Hogna* sp.) capturing a *D. pseudomeridianus* tadpole on the surface of the water of a permanent pond. The spider (length = 6.4 mm) held the tadpole's tail with its chelicerae, but released it when disturbed. The tadpole had a slight tear on its tail and stiffened after being released. The *Hogna* sp. was collected and deposited as a voucher (ZUFRJ 0947). The identification of the spider to species level was not possible, as the copulatory bulb in the pedipalp, an important taxonomic character, was not completely developed, and the species is not a common one in the collecting area. The *D. pseudomeridianus* was also collected (ZUFRJ 14714). To our knowledge, this is the first record of predation upon a *D. pseudomeridianus* tadpole by a spider.

MANUELLA FOLLY (e-mail: manuellafolly88@gmail.com), **SERGIO P. ***HYPSIBOAS ALBOPUNCTATUS* (Yellow-spotted Treefrog). PREDATION.** Herein, we report predation of *Hypsiboas albopunctatus* by the snake *Thamnodynastes hypoconia*. The observation took place at 2230 h on 13 February 2012 (air temperature 27.4°C), in a permanent lentic pond on the edge of a gallery forest in the rural zone of Aparecida do Rio Doce municipality, Goiás state, central Brazil (18.200194°S, 51.069167°W; datum SAD69). We heard alarm calls among shrubs and we observed a *T. hypoconia* capturing a *H. albopunctatus* by the posterior region of the body (Fig. 1). The treefrog stopped the alarm calls before we were able to record them. We continued the observation for 30 min. After predation, the snake continued its foraging activity and did not regurgitate. Specimens were not collected, but photographs were stored in the collections of the Universidade Federal de Goiás. This record reinforces the findings of Bellini et al. (2013. Herpetologica 69:67–79) that anuran amphibians are the main item of *T. hypoconia* diet, especially treefrogs of the family Hylidae. However, to our knowledge this is the first record of *T. hypoconia* feeding upon *H. albopunctatus*.

FIG. 1. Predation on *Hypsiboas albopunctatus* by *Thamnodynastes hypoconia*.

***LEPTOBRACHIUM PULLUM* (Vietnam Spadefoot Toad). EYE COLORATION.** Eye color is often used to delineate frog species in the field and is generally recognized as a reliable taxonomic character (Glaw and Vences 1997. Herpetologia Bonnensis. SEH Proceedings, Bonn, pp. 125–138). This is particularly true of frogs in the genus *Leptobrachium* of the family Megophryidae, where external morphology is highly conserved across species, but eye color tends to vary interspecifically (Dubois and Ohler 1998. Dumerilia 4:1–32).

Leptobrachium pullum was first described as having the upper half of the iris colored scarlet in life (Smith 1921. Proc. Zool. Soc. London 1921:423–440), although more recent observations indicate that the scarlet coloration is restricted to a scleral arc under the palpebrum (Stuart et al. 2011. Zootaxa 2804:25–40). During multiple, extensive field surveys of the Ngoc Linh Nature Reserve, Kon Tum Province, Vietnam (15.08000°N, 107.92700°E;

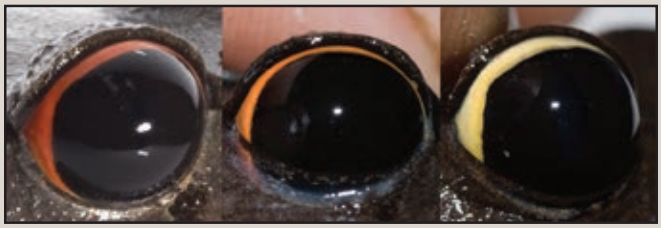

FIG. 1. Variation in sclera coloration in *Leptobrachium pullum* from Ngoc Linh Nature Reserve, Kon Tum Province, Vietnam.

datum WGS84), in 2009 and 2010, *L. pullum* were commonly observed, and photographs and notes were taken regarding eye coloration. While the location of coloration was shown to have little variation among individuals, sclera coloration was variable, ranging from scarlet to pale orange (Fig. 1) even among individuals located within meters of each other. Individuals displayed little other genetic, morphological, or acoustic differentiation (Rowley et al., unpubl. data). Scleral color did not appear to differ between diurnal and nocturnal observations. Nor was there an obvious correlation between sex and/or reproductive status.

Our observations highlight that although eye coloration is a very useful diagnostic character in the genus *Leptobrachium*, care should be taken to record variation within species. These findings may have taxonomic implications for future investigations within species of *Leptobrachium*.

***LITHOBATES SPHENOCEPHALUS* (Southern Leopard Frog). PREDATION.** Adult Southern Leopard Frogs are preyed upon by a wide variety of vertebrates, including a number of bird species (Dodd 2013. Frogs of the United States and Canada.Vol. 1. John Hopkins University Press, Baltimore, Maryland. 460 pp.). The Barn Owl (*Tyto alba*) is the only documented nocturnal avian predator for Southern Leopard Frogs, however another owl species, the Great Horned Owl (*Bubo virginianus*), is known to predate the similar Northern Leopard Frog (*Lithobates pipiens*; Dodd 2013, *op. cit.*). At approximately 1400 h on 04 February 2014 while cleaning out Wood Duck (*Aix sponsa*) nest boxes on Big Lazer Public Fishing Area, Talbot Co., Georgia, USA (32.769199°N, 84.419635°W; datum WGS84), two of us (BG and JR) discovered a single Eastern Screech-owl (*Megascops asio*) in one of the boxes along with 21 Southern Leopard Frog carcasses, including one that was still in the talons of the sleeping owl (Fig. 1). Most of the frogs were fully intact, although a couple had been partially consumed. The box is in close proximity to the shallow headwaters of a 78-ha impoundment, where large numbers of Southern Leopard Frogs could be heard calling. There were no other prey items in the box, and the owl was alone with no signs of nesting. One other Eastern Screech-owl was found in a nest box closer to the dam (and well away from the frog chorus), but that box did not contain any frogs or other cached prey items.

FIG. 1. Eastern Screech Owl (*Megascops asio*) in nest box with cached carcasses of Southern Leopard Frogs (*Lithobates sphenocephalus*).

Eastern Screech-owls are known to cache large quantities of prey, especially in winter months when decay is slowed by cooler temperatures (Phelan 1977. Condor 79:127). Caching for the purpose of feeding young is also known, but no eggs or nestlings were observed and this observation was well before the known onset of nesting in this species (Gehlbach 1995. *In* Poole and Gill [eds.], The Birds of North America, pp. 1–24. American Ornithologists' Union, Washington, DC). Eastern Screech-owls have symmetrically positioned ears suggesting that vision often plays a greater role in prey location than does hearing, the latter of which is more commonly employed by owl species with asymmetrical ears (Gehlbach 1995, *op. cit.*). Thus, the Southern Leopard Frogs may have been encountered visually rather than by sound triangulation toward their vocalizations. Communal oviposition in shallow water by *L. sphenocephalus* is well known (see Trauth 1989. Proc. Arkansas Acad. Sci. 43:105–108) and makes large numbers of mating frogs quite susceptible to predation. To the best of our knowledge, this observation represents the first documented predation event on Southern Leopard Frogs by Eastern Screech-owls, and the only known caching event by this bird species involving only anurans.

We thank Todd Schneider for reviewing the manuscript and providing helpful suggestions for its improvement.

JENSEN**, Georgia Department of Natural Resources, Nongame Conservation Section, 116 Rum Creek Drive, Forsyth, Georgia 31029, USA (e-mail: john.jensen@dnr.state.ga.us).

***LITHOBATES SYLVATICUS* (Wood Frog). EGG PREDATION.** Wood Frogs are abundant amphibians throughout much of northern and northeastern North America, and their eggs are known to be consumed by larval caddisflies (Rowe et al. 1994. J. Herpetol. 28:357–364), *Notophtalmus v. viridescens* (Eastern Red-Spotted Newts; Pitt et al. 2011. Herpetol. Rev. 42:263), larval ambystomatid salamanders (Redmer and Trauth 2005. *In* Lannoo et al. [eds.], Amphibian Declines: The Conservation Status of United States Species, pp. 590–593. Univ. California Press, Berkeley), and leeches (Cory and Manion 1953. Copeia 1953:66). To the best of my knowledge, larval fishflies (Megaloptera: Corydalidae: Chauliodinae) have not been documented as predators of the eggs of *L. sylvaticus* or any other amphibian. Fishflies produce large (up to 65 mm), predatory, aquatic larvae which (along with the larvae of some related megalopterans) are commonly called "hellgrammites" (Flint et al. 2008. *In* Merritt et al. [eds.], An Introduction to the Aquatic Insects of North America, pp. 425–426. Kendall/Hunt Publishing, Dubuque, Iowa).

I collected nine *L. sylvaticus* egg masses from a semi-permanent forest pond in Pennsylvania State Game Lands 176, Centre Co., Pennsylvania, USA (40.765°N, 78.016°W; datum WGS84) in April 2013 for use in a laboratory experiment. Upon return to the laboratory, I noticed that two egg masses had individual fishfly larva (*Chauliodes pectinicornis*) embedded within them. They could only be removed by separating the egg masses by hand. Each larval fishfly was transferred to a small plastic container. Because of how deeply embedded the fishflies were, I suspected they may have been feeding on the eggs. The smaller fishfly (approx. 20 mm) was therefore provided with three *L. sylvaticus* eggs and the larger fishfly (approx. 50 mm) was given nine eggs to test whether they would eat the eggs. After a week, the smaller fishfly was found dead and had not eaten any eggs. However, the larger fishfly had consumed the embryos of seven eggs, leaving the egg jelly relatively intact. I have previously observed *Chauliodes* sp. larvae in at least three other permanent or semi-permanent breeding ponds of *L. sylvaticus*. This is consistent with the long development time of these insect larvae, and many of those I observed were large enough that they had most likely overwintered in the ponds. Together, these observations suggest that fishfly larvae may be important egg predators for *L. sylvaticus* (and potentially other amphibians) in intermediate- to long-hydroperiod ponds.

***LITHOBATES WARSZEWITSCHII* (Warszewisch's Frog). REPRODUCTIVE BEHAVIOR.** There are numerous reports of interspecific amplexus in anurans from many localities (Medina 2013. Herpetol. Rev. 41:123; Pearl et al. 2005. Am. Midl. Nat. 154:126–134; Ritchie et al. 2008. Herpetol. Rev. 39:80). *Smilisca phaeota* and *Lithobates warszewitschii* are common tropical frogs that can be found sympatrically from Honduras to Panama in lowland and premontane wet and moist forest. Here we report the first observation of amplexus between a native hylid and a native ranid in Panama and the first instance of this behavior between these species. At 2003 h on 20 Jan 2011, a male *L. warszewitschii* was observed in amplexus with an adult *S. phaeota* of undetermined sex in the roadside ditches at Río Luis, in the buffer zone of the Santa Fe National Park, Panama (8.68117°N, 81.217796°W; datum WGS84). Weather conditions were clear without rain and it had been two days since the last rain. The frogs were photographed and observed for six minutes. Two hours later, we returned to the same place and they remained in amplexus.

***PHYLLOMEDUSA NORDESTINA* (Leaf Frog) and *PHYSALAEMUS CUVIERI* (Dwarf Frog). INTERSPECIFIC AMPLEXUS.** Interspecific amplexus occurs between amphibians overlapping spatially and temporally (Hobel 2005. Herpetol. Rev. 36:55–56; Hobel 2005. Herpetol. Rev. 36:439–440; Waterstrat et al. 2008. Herpetol. Rev. 39:458), and usually occurs between individuals of the same genus or family (Streicher et al. 2010. Herpetol. Rev. 41:208). On 12 March 2012 at 2000 h, on the banks of an artificial lake in Floresta Nacional do Araripe (Flona-Araripe), Barbalha Municipality, northeastern Brazil (7.36543°S, 39.44061°W; 912 m elev.), we observed interspecific amplexus between two individuals from different families when a female *Phyllomedusa nordestina* (Hylidae) was amplexed by a male *Physalaemus cuvieri* (Leiuperidae) (Fig. 1). Both individuals were trapped inside a tank ca. 1 × 3 m with an artificial depth of about 2.5 m. The tank had a water depth of 40 cm; the specimens were on a fallen log, outside of the water. Streicher et al. (2010, *op. cit.*) reported interspecific amplexus between the hylids *Smilisca baudinii* and *Pachymedusa dacnicolor* and members of this family are known to hybridize (Lamb et al. 1990. J. Evol. Biol. 3:295–309).

This study presents the first report of amplexus between the families Hylidae and Leiuperidae. A likely factor may have been stress due to competition for space associated with the reproductive activity of both species in the area. We thank CNPq who provided the scholarship for S. Ribeiro. The study was authorized by IBAMA permit number 29838-2. Field assistance was provided by O. Filho, G. Sousa, and A. Teixeira.

***PSEUDACRIS ILLINOENSIS* (Illinois Chorus Frog). PREDATION.** *Pseudacris illinoensis* is a fossorial anuran of conservation concern throughout its restricted geographic range. Predators of adults are unknown; confirmed predators of tadpoles include fishes and aquatic insects (Shepard et al. 2005. *In* Lannoo [ed.], Amphibian Declines: The Conservation of United States Species, pp. 484–485. University of California Press, Berkeley). Here, I report snake predation of a *P. illinoensis* tadpole. At 1130 h on 30 April 2013 (sunny, 23°C), I hand-captured a *Nerodia erythrogaster flavigaster* (SVL = 47 cm; total length = 66 cm) in a stagnant, shallow (< 25 cm deep), 1-m wide drainage ditch excavated in a cropfield in Alexander Co., Illinois, USA (precise location withheld). Upon handling, the snake regurgitated a *P. illinoensis* tadpole (total length = 4.1 cm). The tadpole was still alive, indicating recent consumption by the snake. I released the snake and tadpole into the ditch.

JOHN G. PALIS, Palis Environmental Consulting, P.O. Box 387, Jonesboro, Illinois 62952, USA; e-mail: jpalis@yahoo.com.

***RHACOPHORUS RUFIPES* (Red-legged Tree Frog). MAXIMUM ELEVATION.** *Rhacophorus rufipes* is a small anuran (to SVL = 5.0 cm) endemic to the island of Borneo (Inger and Stuebing 2005. A Field Guide to the Frogs of Borneo. Natural History Publications, Kota Kinabalu. 201 pp.). The species dwells in primary forests in lowlands and hilly terrain (elev. up to 250 m), and congregate in low vegetation 1–3 m above the ground to breed (Inger 2005. The Systematics and Zoogeography of the Amphibia of Borneo. Natural History Publications, Kota Kinabalu. 402 pp.). Herein we report a new elevational limit for *R. rufipes*.

Between 1900–2200 h On 29 September 2008, a juvenile *R. rufipes* (SVL = 1.7 cm; mass = 0.5 g) was sampled via opportunistic examination at Sungai Lidan, Bundu Tuhan, Ranau District, West Coast Division, Sabah, Bornean Malaysia (5.9778°N, 116.5298°E, datum WGS84; elev. 1076 m). Air temperature was 18.4°C, and relative humidity was 80.6%. Sungai Lidan is a rocky-bottomed stream with clear and moderately flowing water. The river banks support much vegetation such as rattan, bamboo and wild ginger (Kueh et al. 2011. Herpetol. Rev. 42:91), and thus, provide preferred breeding habitats for *R. rufipes*. The finding represents an extension of elevational limit for *R. rufipes* to the submontane zone. The specimen (HEP00658) was deposited in BORNEENSIS, the Bornean reference collection of the Institute for Tropical Biology and Conservation, Universiti Malaysia Sabah.

Elevational limit change in anurans could be attributed to climate change that enhances both the surrounding abiotic and biotic constraints mainly caused by increasing air temperature, and decreasing precipitation and moisture, and drives anurans uphill (Colwell et al. 2008. Science 322:258–261; Hargreaves et al. 2014. Am. Nat. 183:157–173). Uphill distribution of anurans narrows their geographical range, and subsequently, pushes anurans towards extinction (Toranza and Maneyro 2013. Phyllomedusa 12:97–106). Further studies on the natural history of anurans, in particular their elevational limit, geographical range, and autecology, becomes necessary for effective conservation endeavors.

We are grateful to Agnes James Lintanga for field assistance, Paulus Abas for field transportation, and Haleluyah Retreat Centre for lodgings support. Sampling was conducted under the permission granted by Jawatankuasa Pemegang Amanah Hutan Simpanan dan Tanah Perumahan Bumiputera Kg. Bundu Tuhan, Ranau, to KBH. We also thank the Institute for Tropical Biology and Conservation, Universiti Malaysia Sabah for support.

***RHINOPHRYNUS DORSALIS* (Mexican Burrowing Toad). PREDATION.** *Rhinophrynus dorsalis* ranges from southern Texas, USA and Michoacán, México, south along coastal areas to northeastern Honduras on Caribbean slope, and to Costa Rica in the Pacific slope (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. University of Chicago Press, Chicago, Illinois. 934 pp.); in Costa Rica it is found exclusively in the northwest of the country (Savage 2002, *op. cit.*). At approximately 1750 h on 24 May 2013, at Santa Rosa National Park, Guanacaste Province, Costa Rica (10.83333°N, 85.61667°W; datum WGS84), near a flooded zone of the camping area, we observed a *Pulsatrix perspicillata* (Spectacled Owl) through 10x binoculars perched on a horizontal branch about 5 m high, with a *R. dorsalis* pressed down firmly under its left talon (Fig. 1). The toad was motionless, with its body inflated; from our point of view we were unable to see if it was injured, but the yellow spots on the back and very short limbs leave no doubt about species identification. The bird stayed around 15 min in this position, with its eyes almost closed in the first moments, making slow and gentle sideways movements with its head. Then the owl flew toward a nearby tall

FIG. 1. Predation of *Rhinophrynus dorsalis* (Mexican Burrowing Frog) by *Pulsatrix perspecillata* (Spectacled Owl) in Santa Rosa National Park, Guanacaste, Costa Rica.

tree with its prey in its claws, landing out of sight, preventing us from seeing if the owl consumed the toad. The diet of Spectacled Owls includes a wide range of prey sizes, from medium-sized mammals of several kilograms to birds, lizards, and large insects (Stiles and Skutch 2007. Guía de Aves de Costa Rica. INBio. 680 pp.; Voirin et al. 2009. Edentata 10:15–20). Until now an amphibian has never been reported as a diet item for this species of owl. To our knowledge, this is the first known predator on adults of the rare *R. dorsalis* (Dodd 2013. Frogs of the United States and Canada. Vol. 1. John Hopkins University Press, Baltimore, Maryland. 460 pp.).

We thank to Gilbert Barrantes for inviting us to the field trip, and to Ángel Solís and Luis Sandoval for suggestions on this note.

***SCAPHIOPUS HOLBROOKII* (Eastern Spadefoot). PREDATION.** Herein we document predation on *Scaphiopus holbrookii* by *Canis latrans* (Coyote), an opportunistic predator known to utilize an extensive array of prey (Grigione et al. 2011. Urban Ecol. 14:655–663; Leopold and Krausman 1986. J. Wildl. Manage. 50:290–295). We conducted necropsies of 201 Coyotes collected October 2011–March 2014 throughout Florida, USA. An 11.57 kg male's stomach collected on 03 June 2012 in southeast Columbia Co., Florida contained the remains of an adult male *S. holbrookii* and other items. This is the first report of predation by the Coyote on *S. holbrookii*, although it is has been reported preying on *Spea intermontana* (Great Basin Spadefoot; Dodd 2013. Frogs of the United States and Canada. Vol. 2. John Hopkins University Press, Baltimore, Maryland. 982 pp.). Opportunistic predation of an explosive breeding species is indicative of a generalist predator.

ENGLEMAN**, United States Department of Agriculture, 2820 East University Avenue, Gainesville, Florida 32641, USA (e-mail: randall.l.engleman@aphis.usda.gov).

***SMILISCA DENTATA* (Upland Burrowing Tree Frog). PREDATION.** *Smilisca dentata* is a medium-sized tree frog that lives in burrows. It is endemic to Central México, between southern Aguascalientes and extreme northwestern Jalisco. It is listed by IUCN as Endangered and by Norma Oficial Mexicana as threatened. In recent years, knowledge about *S. dentata* has increased, including information about its distribution, population dynamics, abundance, reproduction, growth, and diet. There are no reports of predators, including any avian predators (Quintero-Díaz and Vázquez-Díaz 2009. Historia Natural de una Rana muy Mexicana. Sociedad Herpetológica Mexicana, Ayuntamiento de Aguascalientes y SEMARNAT. 169 pp.). Here, we report evidence of predation on *S. dentata* by the bird *Lanius ludovicianus* (Loggerhead Shrike), which preys on a wide variety of vertebrates including amphibians, mainly frogs (Lefranc 1997. Shrikes. A Guide to the Shrikes of the World. Yale University Press, New Haven and London. 192 pp.). At 0158 h on 12 November 2009, at Buenavista de Peñuelas, Aguascalientes, México (21.725166°N, 102.300977°W, datum WGS84; elev. 1872 m), we found a dead juvenile *S. dentata* (SVL = 30 mm; UAA-CV-AN229) impaled on barbed wire by *L. ludovicianus* (Fig. 1). We did not observe the bird capturing or killing the frog but we assume it was the result of shrike predation because this behavior is characteristic of the species. To our knowledge, this is the first record of predation on *S. dentata* by *L. ludovicianus*.

FIG. 1. Juvenile Upland Burrowing Tree Frog (*Smilisca dentata*) impaled on barbed wire by a Loggerhead Shrike (*Lanius ludovicianus*), at Buenavista de Peñuelas, Aguascalientes, México.

TESTUDINES — TURTLES

***CARETTA CARETTA* (Loggerhead Sea Turtle). PREDATION.** Coyotes (*Canis latrans*) are generalist predators known to opportunistically utilize an extensive array of species (Leopold and Krausman 1986. J. Wildl. Manage. 50:290–295; Grigione et al. 2011. Urban Ecol. 14:655–663) and are reported to be a nest predator of *Caretta caretta* (Kurz et al. 2012. Oryx 46:223). Herein we provide the first definitive observation of predation on *C. caretta* hatchlings by a Coyote. We conducted necropsies of 201 Coyotes collected October 2011–March 2014 throughout Florida, USA. Twenty-six of the Coyote carcasses were collected from coastal areas during the marine turtle nesting season. The stomach of a 14.1 kg male collected on 26 June 2013 from Archie Carr National Wildlife Refuge, Indian River Co. (27.7953°N, 80.4137°W; datum WGS 84), contained the remains of three *C. caretta* hatchlings (Fig. 1).

FIG. 1. *Caretta caretta* hatchlings found in the stomach of an adult male *Canis latrans*.

BOWLING**, United States Department of Agriculture, 2820 East University Avenue, Gainesville, Florida 32641, USA (e-mail: zachary.t.bowling@aphis.usda.gov).

***CHELYDRA SERPENTINA* (Snapping Turtle). WINTER DROUGHT REFUGIA.** *Chelydra serpentina* inhabits many freshwater habitats including wetlands, rivers, lakes, and ponds (Ernst et al. 1994. Turtles of the United States and Canada. Smithsonian Institution, Washington D.C. 578 pp.) and has been reported to overwinter in shallow water in lakes and streams and muddy marshes in the northern portion of their range (Meeks and Ultsch 1990. Copeia 1990:880–884; Brown and Brooks 1994. Copeia 1994:222–226). Most reports on *C. serpentina* overwintering are from Canada and the northern USA, and there is little published information on the overwintering habits of this species in the southern portion of its range. The following observations were made at the Joseph W. Jones Ecological Research Center at Ichauway in Baker Co., Georgia, USA.

On 27 January 2012, we captured a hatchling *C. serpentina* (CL = 23.8 mm) swimming in a deep muddy pool within a dry, isolated cypress-gum (*Taxodium ascendens* and *Nyssa sylvatica*) wetland that was located approximately 1.5 km from the nearest permanent open water source. The pool was surrounded by Buttonbush (*Cephalanthus occidentalis*) (Fig. 1), and was located within several meters of an American Alligator (*Alligator mississippiensis*) burrow. We investigated the area further when we noticed bubbles emerging from the mud and excavated two more Snapping Turtles, an adult male (CL = 228 mm) and adult female (CL = 320 mm) (Fig. 2), which were buried one on top of the other >30 cm underneath the mud. Both turtles were marked by notching marginal scutes (Cagle 1939. Copeia 3:170–173) and released that same day. We revisited the site on 2 February 2012 and captured two more unmarked adults, both males (CL = 297 and 389 mm, respectively). Thus we observed a total of five different individuals using this single muddy pool in a wetland that had been dry for the previous 12 months. We revisited the wetland again

FIG. 1. Deep muddy pool in dry cypress gum wetland where multiple *Chelydra serpentina* were found overwintering in January-February 2012 and 2013.

FIG. 2. Adult female *Chelydra serpentina* immediately after being excavated from a deep muddy pool on 27 January 2012.

nearly a year later on 14 December 2012 and captured two adult turtles in the original muddy pool, one of which was a marked male that had been captured the previous winter. We searched for other depressions within the wetland on 21 December 2012 and captured a marked female that had moved from the previous area to a different muddy spot under the roots of a pond cypress. At this point the wetland had been dry for 11 months. We investigated another dry cypress gum swamp 7 km N of the original wetland on 16 January 2013, and found an adult male *C. serpentina* (CL = 316 mm) buried under mud in a low area of the wetland near an *A. mississippiensis* burrow. We placed a radio transmitter on this individual and found that he remained in the same spot until 5 February 2013, when the wetland began to fill due to rainfall and the turtle moved to a different area in the wetland. It is unknown whether these low muddy areas were naturally occurring, or whether they were dug or modified by *C. serpentina*.

RACHEL L. KING (e-mail: rking@jonesctr.org), **ELIZABETH M. SCHLIMM,** and **LORA L. SMITH,** Joseph W. Jones Ecological Research Center at Ichauway, 3988 Jones Center Drive, Newton, Georgia 39870, USA.

***CHRYSEMYS PICTA BELLI* (Western Painted Turtle). PREDATION.** Temperate aquatic turtles lay eggs in early summer, which hatch 2–3 months later. Rather than departing natal nests in late summer, hatchlings of many species brumate within these nests and emerge the following spring (Costanzo et al. 2008. J. Exp. Zool. 309A:297–379; Gibbons 2013. J. Herpetol. 47[2]:203–214). From oviposition to initiation of the aquatic phase of their life

history, two periods of heavy predation occur. Many eggs are depredated shortly after nest construction, with the risk decreasing over time (i.e., fresh nests are most vulnerable). Second, many hatchlings are depredated during migration from their terrestrial nests to aquatic habitats. A putative advantage of nest brumation by hatchling turtles is avoidance of potentially heavier predation during fall migration compared to spring migration. Over the winter, mortality from abiotic conditions (e.g., extreme cold) may occur in nests, but mortality from predation has apparently not been previously documented. Here we report apparent predation of hatchling *Chrysemys picta* from natural nests during winter.

As a part of our research on nesting ecology of *C. picta*, we had mapped the location of 16 intact nests near Thomson, Illinois, USA (41.9480°N, 90.1163°W, datum WGS 84; elev. 179 m). These nests were targeted for use in a study examining the influence of nest temperature during winter on hatchling mortality. On 3 November 2013, we carefully removed the soil covering these nests, counted the live hatchlings within each nest, and subsequently reburied these nests. We returned on 30 March 2014 to retrieve hatchlings. Of the 16 nests, 13 had no hatchlings. We infer that nests were depredated (rather than experiencing early emergence by hatchlings) for two reasons. First, soil was nearly frozen in November and still frozen in March, suggesting that hatchlings would have been physically unable to emerge during that period (due to low body temperature and frozen soil). Second, the soil plug that typically covers the opening to each flask-shaped nest was gone and the cavity was void of excess soil. When hatchlings emerge, much of that soil from the plug falls into the nest cavity and the cavity is usually partially filled in with loose soil and eggshell fragments. Instead, these "cleaned out" cavities appeared similar to nests that are depredated by mammals shortly after oviposition in spring and early summer.

Potential predators that are common at our site and active during this winter period include squirrels (*Sciurus carolinensis*), raccoons (*Procyon lotor*), opossums (*Didelphis virginiana*), and mustelids (*Neovision vision, Lontra canadensis*). It was a necessary component of our study to un-cover and re-cover nests in November. Consequently, it is impossible for us to determine whether this disturbance enhanced predator detection of the nests. However, we carefully re-covered nests with soil and leaf litter to minimize visual disturbance, which is the primary cue used by predators during nesting season at our site (Strickland et al. 2010. J. Herpetol. 44:467–470). Additionally, in seven other years of this study using identical methods, we never observed predation at this stage. Our novel predation observation indicates another potential mortality source for hatchling turtles during brumation, a critical early life stage, and challenges a previous assumption regarding the adaptive significance of this neonatal brumation behavior.

TIMOTHY S. MITCHELL (e-mail: timmitch@iastate.edu), **KYLA R. RAND**, and **FREDRIC J. JANZEN,** Department of Ecology, Evolution and Organismal Biology, Iowa State University, Ames, Iowa 50011, USA.

***GOPHERUS MORAFKAI* (Sonoran Desert Tortoise). DRINKING BEHAVIOR.** Water-balance in desert tortoises (*Gopherus* spp.) of the arid Southwest USA has received considerable attention since it was first documented that they will drink free-standing water (Medica et al. 1980. Herpetologica 36:301–304). The tortoises often void bladder contents while being examined for morphological measurements or attachment of radio transmitters (30–60% of tortoises handled; see below), and there is evidence that this loss can have negative fitness consequences (Averrill-Murray 2002. Chelon. Conserv. Biol. 4:430–435). Observations on drinking behavior under natural and artificial (i.e., opportunities provided by humankind) may thus be significant. We initiated a radio-tracking study of Sonoran Desert Tortoises in 2011, and have observed natural and artificially induced drinking behavior in free-ranging subjects that voided bladder contents during processing (Sullivan et al. 2014. Chelon. Conserv.Biol. 17 [*in press*]). Here, we report drinking behavior associated with elimination of urate materials over a very short time period.

FIG. 1. Juvenile *Gopherus morafkai* drinking from container (~ 250 ml) at 0857 h (left), immediately prior to voiding urates (right; note pinkish material immediately posterior to tortoise, surrounding by fluid stained soil) at exactly 0902 h.

FIG. 2. Adult *Gopherus morafkai* drinking from catchment at waterfall following brief rainstorm; note that though the mouth remained closed, the head was completely submerged.

In the summer of 2012, we initially captured and tagged (with radio transmitter) a juvenile tortoise (160 mm straight-line carapace length at first capture) that subsequently (Fall 2013) moved almost 1 km to occupy a dike structure maintained by the Maricopa County (Arizona) Flood Control District (MCFCD). In early March 2014, it was relocated to the eastern slope of the Union Hills, exactly four weeks prior to the observations reported herein, as a result of requests by MCFCD personnel (maintenance of the dike required application of herbicides and associated use of heavy construction equipment). When the tortoise was moved, it voided (estimated as approximately 25–50 ml of fluid), and we were concerned that this individual might be compromised.

Thus, when we released the tortoise, we provided an opportunity for drinking by filling a series of rocky catchments at its release site, a small wash with many recently used tortoise refuges nearby, but we observed that it bypassed the artificial pools, and entered a caliche formation refuge without taking any water. Consequently, in the absence of rainfall, each subsequent tracking event was approached as an opportunity to rehydrate the subject (e.g., if found within a refuge, it was deemed unavailable for watering, etc.). On 20 April we located the individual in shade, in a relatively flat area in which we could place a small, round container of water (125 mm diameter, 20 mm deep), immediately anterior to the tortoise, in the hope it would drink despite the artificial nature of the situation.

The container was initially placed at 0840 h (air temp = 22°C) in the shade of large (2 m height) Palo Verde along a small wash on the eastern slopes of the Union Hills (33.72909°N; 112.05661°W, datum NAD27; elev. 527 m) in Maricopa Co., Arizona. Initially, the tortoise withdrew but one of us remained crouched ~ 1 m away so that we could provide additional water and reposition the container (which was tipped over twice by the subject and repositioned each time immediately to its front). On the third placement, after 15 min had elapsed, the tortoise allowed its head to be sprinkled with water as the container was refilled for the third time, and this seemed to finally stimulate a drinking response. The individual lowered its head into the water, tilting it at an almost 90° angle to the ground, and began to drink (Fig. 1), apparently through the nares. As with naturally observed drinking events (Fig. 2), the tortoise submerged the nares and mouth and did not open the mouth significantly; the throat region pulsed regularly during the entire process, once every few seconds. It consumed the entire contents, measured as ~ 200 ml, in 5 min and 11 sec, and then voided a dark, tea stained liquid (estimated as ~ 100 ml based on comparative estimates of water required to moisten a similar sized patch of nearby soil), and a viscous paste of pinkish urates (Fig. 1). The urates were passed immediately upon cessation of drinking, as it lifted its head from the water container, just over 5 min since the initiation of drinking.

Our observations suggest that researchers, if persistent, can achieve re-hydration of subjects that have voided during processing, and presumably mitigate increased mortality effects documented by Averrill-Murray (*op. cit*). In addition, our observations reveal that hydration allows for extremely rapid "flushing" of urate materials and a presumed reduction of any negative physiological consequences of their retention.

Special thanks to Keith and Justin Sullivan and Darci, the cautious turtle tracking canid.

BRIAN K. SULLIVAN and **ELIZABETH. SULLIVAN**, School of Mathematical and Natural Sciences, Arizona State University, PO Box 37100, Phoenix, Arizona 85069, USA (e-mail: bsullivan@asu.edu).

GOPHERUS POLYPHEMUS **(Gopher Tortoise). PREDATION.** Known ophidian predators of *Gopherus polyphemus* eggs and hatchlings include: *Agkistrodon piscivorus*, *Crotalus adamanteus*, *Coluber flagellum*, and *Drymarchon corais* (Ernst and Lovich 2009. Turtles of the United States and Canada, 2nd ed., The Johns Hopkins University Press, Baltimore, Maryland. 827 pp). Additionally, Douglas and Winegarner (1977. J. Herpetol. 11:236–238) state, "Carr (1963) implied the pine snake, *Pituophis melanoleucus*, as a potential predator of the young [*G. polyphemus*] in Florida"; however, upon reviewing Carr 1963 (The Reptiles. Times Inc., New York. 192 pp.) we found no such implication. Herein we report a novel predator of *G. polyphemus* eggs.

On 16 July 2013 at 1210 h an adult female *P. m. lodingi* (SVL = 143.1 cm; tail length = 17.8 cm, 1030 g) was observed crossing a dirt road in the southwestern corner of the Camp Shelby Joint Forces Training Center, De Soto National Forest, Perry Co., Mississippi, USA. While processing the snake it was noted that she was a recapture (original capture date: 9 September 2004, estimated age and SVL at first capture 4 y.o. and 121.1 cm; respectively), overtly gravid, and the decision was made to retain the animal in captivity until oviposition (which took place 6 d later; clutch size = 5 eggs). On 12 September 2013 the snake defecated in the terrarium that she was temporarily housed in, and while examining the scat contents, the inner shell membrane of a *G. polyphemus* egg was found (pieces of the outer shell membrane were present where the egg had been folded over during ingestion/ digestion). To the best of our knowledge this is the first instance of a *G. polyphemus* in the diet of *P. melanoleucus*.

JAMES R. LEE,, The Nature Conservancy, Camp Shelby Joint Forces Training Center, CSJFTC-ENV; Building 6530, Camp Shelby, Mississippi 39407, USA (e-mail: jlee@tnc.org); **STEPHEN C. RICHTER**, Department of Biological Sciences, Moore 349, Eastern Kentucky University, 521 Lancaster Avenue, Richmond, Kentucky 40475, USA (e-mail: stephen.richter@eku.edu).

GRAPTEMYS OUACHITENSIS **(Ouachita Map Turtle). INTERACTION WITH PREDATOR.** The risk of Raccoon (*Procyon lotor*) predation encountered by many North American freshwater turtles during terrestrial nesting forays (reviewed in Ernst and Lovich 2009. Turtles of the United States and Canada. Johns Hopkins University Press, Baltimore, Maryland. 840 pp.) has been suggested to have played a role in nesting schedules (e.g., sensu Congdon et al. 1983. Herpetologica 39:417–429), with larger turtle species that possess sufficient defense mechanisms (e.g., *Chelydra serpentina*, *Emydoidea blandingii*) having a wider temporal overlap with the largely crepuscular or nocturnal raccoons than smaller, diurnally nesting forms (e.g., *Chrysemys picta*). However, it is also understood that mammalian predation risks on adult turtles are but one of several factors that shape reproductive activity patterns (e.g., Bowen et al. 2005. J. Zool., London 267:397–404), including desiccation and temperature-related physiological constraints, and diurnal avian predation risks on turtle eggs and possibly adults of smaller species. The ultimate behavioral pattern that emerges for each species may thus reflect a complex balance of sometimes opposing selection pressures, making interpretations difficult (e.g., the nocturnal nesting of *Clemmys guttata*, one of the smallest of North American emydids and presumably one of the most vulnerable species to nocturnal mammalian predators (Litzgus and Brooks 1998. J. Herpetol. 32:252–259).

It has been suggested that the intensity of Raccoon predation on adult turtles may be skewed toward smaller individuals in some populations (e.g., West-central Illinois *Trachemys scripta*, Tucker and Janzen 1999. Am. Midl. Nat. 141:198–203). However, turtle size did not appear to influence predation likelihood for the large emydid, *Pseudemys concinna suwanniensis*, predated by the small–medium sized Raccoon races of northern Florida (Jackson and Walker 1997. Bull. Florida Mus. Nat. Hist. Biol. Sci. 41:69–167). Raccoon predation risks on nesting female turtles are also likely to be context dependent, differing in intensity with, among others factors, geographic location, meteorological effects on turtle and predator activity schedules, and time spent nesting, size of nesting areas and location within the surrounding land matrix, and local raccoon densities and behavior.

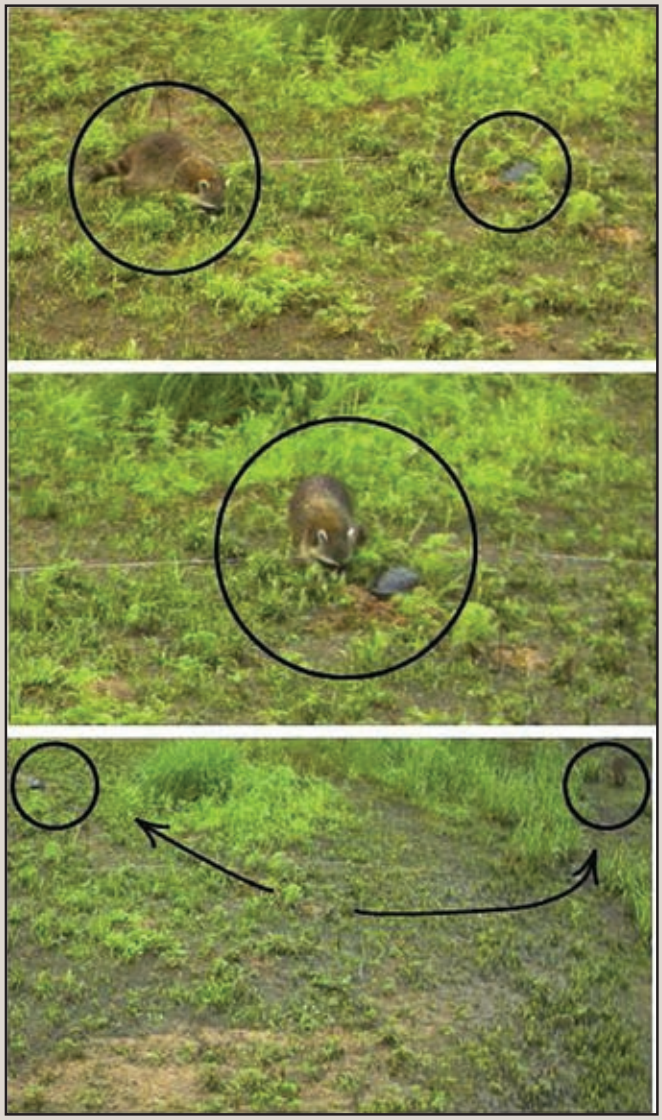

FIG. 1. Images one minute pre-encounter (top), encounter (middle) and one minute post-encounter (bottom) of nesting Ouachita Map Turtle (*Graptemys ouachitensis*) and Raccoon (*Procyon lotor*) interaction; 1940–1942 h, 15 June 2013, Iowa County, Wisconsin, USA.

This note reports observations of diurnally active Raccoons in camera-documented proximity to female Ouachita Map Turtles (*Graptemys ouachitensis*)—without evidence of turtle predation—during June 2013 at a Wisconsin River nesting site in Iowa County, Wisconsin, USA (described as Site A in Geller [2012. Chel. Conserv. Biol. 11:206–213]). Images were obtained using digital trail cameras (1 Reconyx HC600 HyperFire™ programmed to take time-lapse images at 1-min intervals and motion-triggered series; 3 Reconyx Silent Image™ RM30, with 5-min time-lapse intervals and motion-triggered series).

In an encounter on 15 June 2013 (1940–1942 h), a Raccoon detected a turtle approximately 16 minutes after beginning nest construction and possibly just prior to egg deposition, spent < 2 minutes near the nesting turtle, causing nest abandonment, and then both the Raccoon and the turtle departed the field-of-view on separate trajectories (Fig. 1). In Fig. 1 (middle), the raccoon is rearward of the nesting turtle and apparently focused on the ground, indicating an interest in turtle eggs rather than the turtle itself. In other instances, individual Raccoons were either present in the same camera field-of-view with transient turtles (15 June 2013) or within a few minutes of other nesting turtles (16 and 22 June 2013) without camera or subsequent field evidence (e.g., predated turtles near monitored areas) of physical interaction.

The influence of year-to-year variation in Raccoon activity schedules on the likelihood of turtle interaction was demonstrated at this site by the dramatic increase in diurnal Raccoon presence during the 2013 nesting season relative to previous years (31 vs. 2008–2011 mean of 2.25 raccoons, respectively, during 0600–1900 h; raccoon images separated by ≥ 30 min regarded as separate occurrences). The high visitation rates by nest foraging Raccoons and associated short nest survival times at this well-used nesting site (Geller 2012. Chel. Conserv. Biol. 11:197–205) suggest that turtle eggs deposited in this area are a known, dependable food resource to the local Raccoon population. While Raccoon predation on adult *Graptemys* has been reported elsewhere (Lindeman 2013. The Map Turtle and Sawback Atlas: Ecology, Evolution, Distribution, and Conservation. Univ. Oklahoma Press, Norman. 460 pp.), the lack of observed predation on adult turtles noted here may reflect the presence of this protein-rich resource in meeting Raccoon caloric demands (at least for diurnally foraging individuals with the potential to appropriate relatively high proportions of nests), and/or a potentially higher cost/benefit ratio of predating these medium-sized map turtles (females 163–242 mm straight line carapace length [Vogt 1980. Tulane Stud. Zool. Bot. 22:17–48]) relative to excavating and consuming eggs.

I thank John Iverson for his input and review of this report.

***PHRYNOPS TUBEROSUS* (Peters' Side-necked Turtle). HATCHLING SIZE.** *Phrynops tuberosus* is a medium-sized (to 30 cm carapace length) chelid turtle found in Guyana, the southeastern portion of Venezuela, Suriname, French Guyana, the eastern Amazon basin, and northeastern Brazil (Ernst and Barbour 1989. Turtles of the World. Smithsonian Inst. Press, Washington, DC. 313 pp.; Bonin et al. 2006. Turtles of the World. Johns Hopkins University Press, Baltimore, Maryland. 416 pp.). This species is used for food and medicinal purposes by humans (Alves et al. 2012. J. Ethnobiol. Ethnomed. 8:1–29), but much of its natural history remains poorly known. Here we report the first morphometric data for hatchling *P. tuberosus*.

On 20 November 2013, during faunal rescue operations resulting from the Project of Integration of São Francisco River (PISF), we collected three turtle eggs, hitherto of unknown species. The eggs were located in an area that will be the site of a dam of the Morros Reservoir (7.14726°S, 38.59988°W), in the municipality of São José de Piranhas, state of Paraíba, Brazil. The collection site was a small area with an accumulation of water (approximately 5 m long × 2 m wide), which was already drying, where a tractor was clearing low vegetation that had formed a dense cover over the ground. Of the three eggs collected, two remained intact and were placed in a folded tissue, which was wrapped in a plastic bag sealed with adhesive tape, and taken to the hotel hosting the rescue team. In this condition the eggs were kept at ambient temperature and humidity. On 23 November 2013 two hatchlings were found (Fig. 1) between the tissue and plastic bag. They were taken to the Laboratório de Morfofisiologia of the Núcleo de Ecologia Molecular (NECMOL) in the Centro de Conservação e Manejo de Fauna da Caatinga (CEMAFAUNA-CAATINGA)

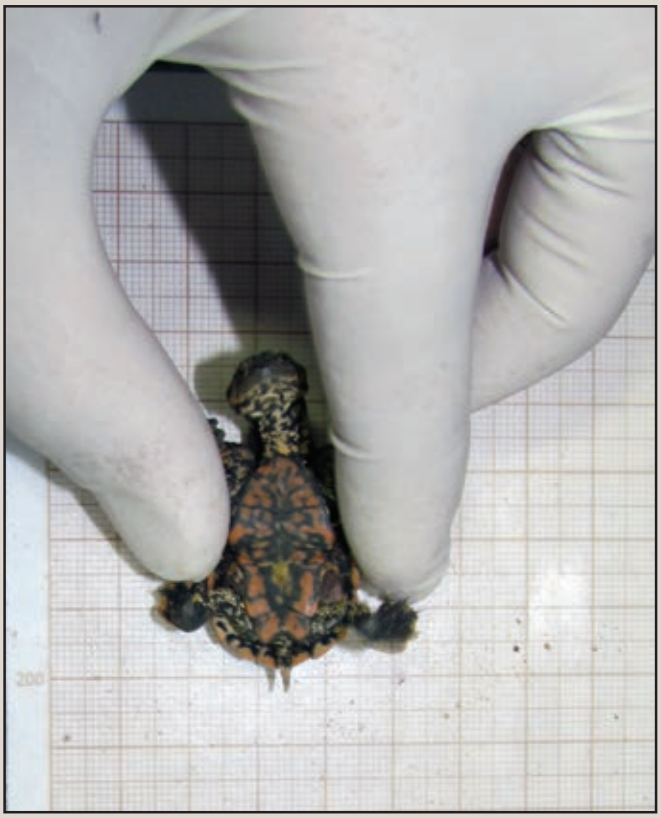

FIG. 1. Plastron view of hatchling *Phrynops tuberosus* (carapace length: 31.9 mm, plastron length: 24.9 mm).

where they were identified (Ernst and Barbour, *op. cit.*; Bonin et al., *op. cit.*), and measured using a digital caliper (precision = 0.01 mm); body mass was measured with a precision balance (1 g).

Morphometric data for the two hatchlings follows: carapace length (CL of turtle 1: 31.9 mm, CL of turtle 2: 30.3 mm), carapace width (CW1: 22.8 mm, CW2: 19.7 mm), shell height (SH1: 10.5 mm, SH2: 9.8 mm), plastron length (PL1: 24.9 mm, PL2: 23.8 mm), plastron width (PW1: 15.4 mm, PW2: 13.8 mm), body mass (BM1: 4.3 g, BM2: 3.9 g). In comparison, Ferreira Júnior et al. (2011. Zoologia 28:571–576) reported the weight and size for 83 hatchlings of the closely related *P. geoffroanus*, hatched in natural nests on sandy beaches along the Upper Xingu River in the Brazilian Amazon Basin: mean carapace length (38.3 ± 2 mm; range = 31.5–41.3), carapace width (30.1 ± 1.83 mm; range = 24.7–33.6), height of shell (13.9 ± 1.06 mm; range = 11.3–16.1), and mean hatchling mass (9.1 ± 1.4 g; range = 6–11.5).

The specimens of *P. tuberosus* (MFCH 3352–3353) were deposited in the Herpetological Collection of the Centro de Conservação e Manejo de Fauna da Caatinga (CEMAFAUNA-Caatinga/UNIVASF), Petrolina, Pernambuco, Brazil. We thank the Ministério da Integração Nacional for financial support. IBAMA provided the collecting permit (# 95/2012 Process n° 02001.003718/94-54).

***PODOCNEMIS SEXTUBERCULATA* (Six-tubercled Amazon River Turtle). MOVEMENT.** *Podocnemis sextuberculata* is a small Amazonian freshwater turtle found in Colombia, Brazil, and Peru (Vogt 2008. Amazon Turtles. Biblos, Lima, Peru. 104 pp.). This species has a dynamic movement pattern influenced by the variable hydrological regime of its habitat (Fachin-Terán et al. 2006. Chelon. Conserv. Biol. 5[1]:18–24). During the high water season, individuals remain in lakes and flooded forest. As water levels begin to fall, turtles move into the main river channel, where adult males and females concentrate in deep pools near the nesting beaches (Fachin-Terán et al. 2006, *op. cit.*; Vogt 2008, *op. cit.*). As the water level again starts to rise after the nesting season, the turtles return to the lakes and flooded forest.

Since 2006, RCV and collaborators have been systematically monitoring the population structure and movement patterns of freshwater turtles in the Trombetas River Biological Reserve (1.25°S, 56.83°W; WGS84), a reserve maintained by the Brazilian government in Oriximiná, Pará State, Brazil. According to monitoring results, the *P. sextuberculata* female recapture rate is low and the sex ratio is always male-biased. To understand these results, we conducted a radio telemetry study to investigate the post-nesting behavior of female *P. sextuberculata*.

The field study was conducted from September to December, in 2010, 2011, and 2012. This is the dry season in the Trombetas River region, when the water level is lowest and females are easily captured on the nesting beaches or in nearby deep pools along the main river channel. We captured eleven *P. sextuberculata* post-nesting females by hand or using trammel nets; for each we attached a radio transmitter (AVM Instrument Company, California, USA; MP2 Model) on 5th central carapace scute with Turbolit, an epoxy based product. The 164–165 MHz transmitters had a programmed battery life of one to two years. Movements based on radio telemetry were summarized for each individual and all the distances were measured in a straight line from release point to transmitter location point. The females had a mean straight-line carapace length of 289.63 mm (N = 11; SD = 9.83; 286–318 mm) and mean mass of 2805 g, SD = 292 (2150–3200 g).

In 2010, 2011, and 2012 field seasons, five, two, and four females, respectively, were monitored using radio telemetry. In 2010, four turtles were located 98 times, up to ten days after release. After this period we lost the signals. In 2011, one turtle was located three times during six days (last location: 5 October 2011) and the other was located five times during ten days (last location: 8 October 2011). On 22 November 2012 both of the females from 2011 as well as the four marked in 2012 were located in the Pracuuba Stream, a tributary of Erepecu Lake, at a water depth of 1.06–2.54 m (Fig. 1). This area is 10 km in straight line distance from the last location noted in 2011, but these turtles move via water, so the actual distance is about 60 km, following the most direct route within the lake and river channels (Fig. 2).

Females with radio transmitters attached in 2012 were located 29 times during 3 months. One turtle was released on 26 September 2012 and monitored for 12 days until 7 October 2012. Forty-five days later, on 22 November 2012, this turtle was found 10 km away from the last location in the Paracuuba Stream together with the other three marked in 2012 and the two from 2011. All were found in the same small area, where they were probably feeding on mollusks. Notably, we found two of the 2012 females back at

FIG. 1. Pracuuba Stream, a tributary of Erepecu Lake, at a water depth of 1.06–2.54 m, both of the females from 2011 as well as the four marked in 2012 were located here on 22 November 2012.

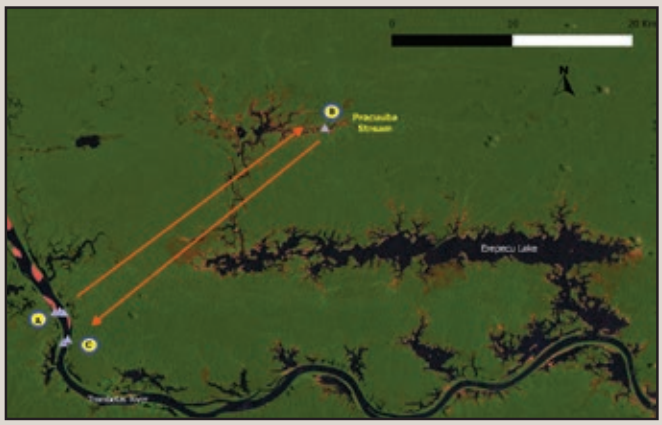

FIG. 2. Satellite image of movement patterns of the *Podocnemis sextuberculata* females from the nesting beach to Pracuuba Stream in Erepecu Lake.

the nesting beaches on 6 December 2012 in the Trombetas River where they were originally marked during the nesting season. This involved a displacement of 60 km upstream against the current in 12 days or less. Nesting had terminated in October, and these females had returned to the nesting beach at the time their eggs were due to hatch. Behavioral interactions and audible communications between adults and hatchlings have recently been described for the Giant South American River Turtle (*Podocnemis expansa*). It is now thought that adults of this species wait off the nesting beaches for their hatchlings to emerge and then migrate downstream with them (Ferrara et. al. 2014. Herpetologica, *in press*). Thus, the possibility of group social behavior must also be studied in *P. sextuberculata*.

Gathering movement data and understanding the detailed patterns of turtle movements are necessary for recommending management or conservation programs for them. Nesting beach requirements are well known, but this new data on home range, which is apparently nearly as great as that of the larger *P. expansa*, is a notable discovery. We lost track of the females marked in 2011 and 2012 because they had ranged much farther than predicted, and into a habitat that they previously were not known to use. Our data show that post-nesting *P. sextuberculata* females migrate to particular feeding areas and that at least some of them return to the nesting beaches at the time the hatchlings are emerging. Describing the social behavior in this species, including the possibility of vocal communication, will warrant further research.

ELP, RAS, FSR were supported by scholarships from Conselho Nacional de Pesquisa e Desenvolvimento (CNPq) from the PCI Program - INPA. Field work was financially supported by Arpa and Petrobras Ambiental Program. All research was authorized by IBAMA permits to RCV.

***RHINOCLEMMYS AREOLATA* (Furrowed Wood Turtle). MAXIMUM SIZE AND MASS.** The maximum size previously reported for *Rhinoclemmys areolata* is a straight-line carapace length of 20.7 cm, obtained from an intact shell of a gravid female found in Belize (Platt et al. 2004. Herpetol. Rev. 35:383). The maximum body mass reported for the species seems to be also from a female from Belize weighting 930 g (Vogt et al. 2009. Chelon. Res. Monogr. 5:022.1–022.7).

On 19 February 2014, during turtle sampling at Pochote (17.76236°N 91.73963°W, datum WGS84; elev. < 10 m), Emiliano Zapata Municipality, State of Tabasco, México, we measured a captive female *R. areolata* with a carapace length of 24.0 cm and a body mass of 1550 g. Other parameters measured were the plastron length (22.7 cm), carapace high (84.33 mm), carapace maximum width (15.8 cm), and head width (30.7 mm). The owners of the turtle told us that the specimen was collected between the Chaschoc lagoon and Nuevo Pochote, about 8 km N of this locality. On 5 March 2014, we measured another captive female of *R. areolata* at the locality of La Isla (17.75756°N, 91.73421°W, datum WGS84; elev. < 10 m) in the same municipality, which surpassed the maximum size given by Platt et al. (2004, *op. cit.*). The individual had a carapace length of 21.1 cm and a mass of 1440 g. The other parameters were plastron length (19.3 cm), carapace high (63.31 mm), carapace maximum width (15.1 cm), and head width (26.0 mm). These females and other individuals of *R. areolata* are kept as pets by local people, and this seems to be the principal use of this species by humans in the region.

This study was logistically and financially supported by the Secretaría de Energía, Recursos Naturales y Protección Ambiental (SERNAPAM), Consejo Nacional de Ciencia y Tecnología (CONACYT) and Gobierno del Estado de Tabasco through the project Fondo Mixto TAB-2012-C28-194316. Research permit (SGPA/DGVS/11742/13) was issued by the Secretaría de Medio Ambiente y Recursos Naturales de México.

***SIEBENROCKIELLA LEYTENSIS* (Philippine Forest Turtle). DIET.** *Siebenrockiella leytensis* is an endemic geoemydid

FIG. 1. *Siebenrockiella leytensis* fecal pellets with snail shell fragments (EYS 266; square = 5 mm).

FIG. 2. *Siebenrockiella leytensis* fecal pellets with rice grains (EYS 265; square = 5 mm).

turtle from Palawan and Dumaran Island, Philippines. Its diet is known to consist of fish, shrimp (genus *Macrobrachium*), crabs, snails (*Pomacea canaliculata* and family Thiaridae), algae, and fruits (genus *Ficus*) (Diesmos et al 2012. Chelon. Res. Monogr. 5:066.1–9; Diesmos et al 2008. Chelon. Conserv. Biol. 7:157–177). Here we report on additional food items in the diet of this turtle.

While conducting wildlife trade research in a Metro Manila pet center, EYS collected seven fecal pellets between 28 November 2012 and 17 December 2012 from multiple wild-caught *S. leytensis* (SCL 71–193 mm; gender undetermined; N = 30). Snail shell fragments were identified as *Pomacea canaliculata* (an invasive species in the Philippines), *Melanoides* sp. (family Thiaridae) and *Planorbis brunneus* (family Planorbidae) (Fig. 1). Six out of seven fecal pellets also contained rice grains (*Oryza sativa*) (Fig. 2). To our knowledge, this is the first report of rice in the diet of a Philippine turtle.

Voucher specimens were preserved in 70% ethanol and deposited in the herpetological collection of the Philippine National Museum (EYS 263–265, and EYS 267) and malacological collection of the University of the Philippines, Diliman (EYS 262, EYS 266, and EYS 271).

CROCODYLIA — CROCODILIANS

***ALLIGATOR MISSISSIPPIENSIS* (American Alligator). CANNIBALISM.** Cannibalism, broadly defined as the consumption of conspecifics through predation or scavenging (Fox 1975. Annu. Rev. Ecol. System. 6:87–106; Polis and Myer 1985. J. Herpetol. 19:99–107), has been reported to occur in several species of crocodilians (Pitman 1941. Uganda J. 9:89–114; Polis and Myer, op. cit. and references therein; Messel and Vorlicek 1986. Austral. Wildl. Res. 13:71–111; Richards and Wasilewski 2003. Herpetol. Rev. 34:371; Somaweera et al. 2013. Herpetol. Monogr. 27:23–51), including *Alligator mississippiensis* (Giles and Childs 1949. J. Wildl. Manage. 13:16–28; Rootes and Chabreck 1993. Herpetologica 49:99–107; Delany et al. 2011. Herpetologica 67:174–185). Cannibalism among crocodilians remains poorly understood, but suggested causes include food availability, population density, demographic factors, and habitat characteristics (Rootes and Chabreck, *op. cit.*; Delany et al., *op. cit.*). Cannibalism among crocodilians may regulate population size and serve as an important energy loop (Polis 1981. Annu. Rev. Ecol. System. 12:225–251; Rootes and Chabreck, *op. cit.*; Delany et al., *op. cit.*). Here we report three field observations of apparent cannibalism among wild *A. mississippiensis* from two locations in Louisiana, USA.

The first observation was made during July 1983 on Rockefeller Wildlife Refuge (Cameron Parish, Louisiana, USA) when RME found the carcass of a small alligator (total length [TL] approximately 1.3 m) floating in a drainage ditch adjacent to an active alligator nest. When a coworker attempted to retrieve the carcass with a noose pole, the nesting female alligator (TL ca. 2.1 m) swam rapidly across the ditch from the nest site, seized the carcass at the base of the tail, and swam back to the nest. Once at the nest, the female climbed up the bank dragging the carcass partially out of the water. The nesting female was identified by a series of marked caudal scutes as an escapee from a captive breeding enclosure on the refuge. Based on the behavior of the nesting female, we assume she was responsible for the death of the smaller alligator. Because female alligators actively defend nests against potential predators (Hunt and Ogden 1991. J. Herpetol. 25:448–453), the heightened aggressiveness of the attending female may have played a role in this incident. The ultimate fate of the alligator carcass could not be determined, but we suspect the female may have cached it nearby (Doody 2009. Herpetol. Rev. 40:26–29).

The second observation occurred on 24 June 2013 (1319 h) when PLT and a co-worker were flying in a helicopter at an altitude ≤ 46 m marking alligator nests as part of an on-going research project at Rockefeller Wildlife Refuge. While flying at low level over the Superior Canal System along Josephine Bayou, a large adult alligator was observed beside the carcass of a smaller adult; the latter was floating ventral side up and the tail was missing, presumably eaten by the larger alligator. The bloated condition of the carcass suggested the alligator had been killed at least 24 h prior to our observation. The TL of the larger and smaller alligator were estimated to be 3.3 m and 1.8–2.1 m, respectively.

PHOTOGRAPH BY PHILLIP L. TROSCLAIR, III

FIG. 1. An American Alligator (TL ca. 3.3 m) consuming the carcass of a smaller conspecific near Lake Des Allemands, St. Charles Parish, Louisiana.

Because adult female *A. mississippiensis* in Louisiana rarely exceed 2.7 m in TL (Joanen et al. 1984. Proc. Annu. Conf. Southeast Assoc. Fish Wildl. Agencies 38:201–211), the body size of the larger alligator strongly suggests it was a male.

The third observation was made on 1 July 2013 (1425 h) while PLT and JTL were flying transects and counting alligator nests as part of an annual population census of *A. mississippiensis* in coastal Louisiana (McNease et al. 1994. *In* Crocodiles: Proceedings of 12th Working Meeting of IUCN/SSC Crocodile Specialist Group, pp. 108–120, IUCN Publications, Gland, Switzerland). While flying in a helicopter at an altitude of approximately 46 m over an extensive freshwater marsh surrounding Lake Des Allemands (St. Charles Parish), a large alligator (TL ca. 3.3 m) was observed with the carcass of a smaller alligator held between its jaws (Fig. 1). The larger alligator was consuming the carcass when interrupted by the low-flying aircraft. The condition of the carcass suggested the smaller alligator had been killed only a short time (< 12 h) before our arrival. Although the body size of the carcass was difficult to determine because of extensive damage to the head and torso, we estimate its TL was between 1.8 and 2.1 m. As the helicopter hovered overhead, the larger alligator grasped the carcass and submerged beneath the floating marsh vegetation. As in the previous 2013 observation, the body size of the larger alligator indicated it was most likely a male.

Our observations of cannibalism by *A. mississippiensis* are noteworthy for several reasons. First, previous reports have inferred cannibalism from the presence of alligator remains or metal marking tags in stomach contents (Giles and Childs, *op. cit.*; Delany and Abercrombie 1986. J. Wildl. Manage. 50:348–352; Platt et al. 1990. Northeast Gulf Sci. 11:123–130; Rootes and Chabreck, *op. cit.*; Delany et al., *op cit.*), and direct observations of cannibalistic behavior among wild *A. mississippiensis* appear lacking in the scientific literature. Such observations are important because although stomach contents analyses are useful for determining dietary composition, this methodology reveals little about the foraging mode (i.e., predation vs. scavenging), which is crucial to understanding cannibalism as a trophic pathway (DeVault and Phodes 2002. Acta Theriol. 47:185–192). In this regard our observations are significant, as all three appear to be instances of predation rather than scavenging, a foraging mode that is common among crocodilians (Pitman, *op. cit.*; Atwell 1959. African Wildl. 13:13–22; Platt et al. 2007. Southwest. Nat. 52:310–317). Second, our observations occurred at two widely separated (> 200 km) locations and when combined with other reports from Louisiana (Giles and Childs, *op. cit.*; Taylor 1986. Proc. Ann. Conf. Southeast. Assoc. Game Fish Comm. 40:338–341; Platt et al., *op. cit.*; Rootes and Chabreck, *op. cit.*) suggest that cannibalism probably occurs in alligator populations throughout the state. Finally, our observations support the conclusion of Rootes and Chabreck (*op. cit.*) that large adult alligators (TL > 2.73 m) prey almost exclusively on large subadult and small adult conspecifics (TL = 1.2–2.1 m) rather than juveniles (TL < 1.2 m).

SQUAMATA — LIZARDS

***AGAMA ANCHIETAE* (Anchieta's Agama). DIET.** *Agama anchietae* occurs from southern Democratic Republic of the Congo, south through Angola, Namibia, and into northwestern South Africa. Although little is known about the diet of *Agama anchietae*, southern African lizards in the genus *Agama* are known to feed heavily on ants, including ants in the genera *Pheidole*, *Crematogaster*, and *Anoplolepis* (Branch 1998. Field Guide to Snakes and Other Reptiles of Southern Africa. Struik Publishers, Cape Town. 399 pp.; Heideman 2002. J. Herpetol. 36:515–520). The only published dietary information for *A. anchietae* is that it feeds on termites and small beetles (FitzSimons 1943. The Lizards of South Africa. Transvaal Museum, Pretoria. 528 pp.). Recent observations made in the Swakop River Valley, in the west-central part of the Namib-Naukluft National Park, Namibia (22.70014°N, 14.91606°W, WGS84; elev. 194 m) extend the known diet of *A. anchietae*. On 12 May 2013 at 0949 h an adult female *A. anchietae* was noosed on a rocky hillside. Body temperature immediately after capture was 34.8°C, ground surface temperature in full sun was 33.9°C, and air temperature 10 mm above ground surface was 25.9°C. Upon capture the lizard regurgitated a large bolus of small ants (> 50 ants) that were later identified to be from the *Lepisiota capensis* species group (Marsh 1986. Madoqua 14:333–344; www.antsofafrica.org, accessed 17 January 2013). Upon closer examination it was revealed that the lizard had been situated adjacent to, and feeding from, a large aggregation of *Lepisiota* ants on the rock face. To our knowledge this is the first report of *A. anchietae* feeding on this small, ubiquitous ant, and adds to the paucity of data concerning its diet.

We thank Theo Wassenaar of Namibia's Gobabeb Research and Training Centre for support and the Namibian Ministry of Environment and Tourism for permission to work in the Namib-Naukluft National Park.

LEASE**, School of Physiology, Faculty of Health Sciences, University of the Witwatersrand, Parktown, 2193, Johannesburg, South Africa.

FIG. 1. Predation of *Amphisbaena vermicularis* by *Apostolepis cearensis*.

***AMPHISBAENA VERMICULARIS*. PREDATION.** The natural history of amphisbaenians is poorly known, probably due to their fossorial habits (Gans and Amdur 1966. Proc. California Acad. Sci. 33:69–90; Filho et al. 1996. Scitientibus 14:57–68). *Amphisbaena vermicularis* is probably a species mainly of Caatinga and Cerrado that just enters eastern Amazonia (Hoogmoed and Ávila-Pires 1991. Bol. Mus. Para. Emílio Goeldi. sér. Zool. 7[1]:77–94), known from the Brazilian states of Pará to Minas Gerais, Mato Grosso, and Mato Grosso do Sul (Gans and Amdur, *op. cit.*; Vanzolini et al. 1980. Répteis das Caatingas. Acad. Bras. de Ciênc., Rio de Janeiro. 161 pp.; Uetanabaro et al. 2007. Biota Neotropica 7:279–289). Here, we report predation of *A. vermicularis* by the snake *Apostolepis cearensis* (Fig. 1).

On 1 February 2012 at 0700 h in the semiarid region of Bahia (9.876173°S, 41.07277°W), about 50 km from the city of Sobradinho we photographed an *Apostolepis cearensis* consuming an *Amphisbaena vermicularis* in the open and above ground. The recording took place at the time the snake had grabbed the head of amphisbaenian, which in turn revolved around its own axis in an attempt to escape the attack. *Apostolepis* snakes are known predators of amphisbaenians (Gomes et al. 2005. Herpetol. Rev. 36:170). There is one record of predation of *A. vermicularis* by *Micrurus ibiboboca* (Lisboa and Freire 2010. Herpetol. Rev. 41:73). *Apostolepis cearensis* can prey on small snakes such as *Tantilla melanocephala* (Mesquita et al. 2009. Herpetol. Rev. 40:440), but amphisbaenians have not been reported. This is a new predator record for *A. vermicularis* and also a new record of prey for *A. cearensis*.

***ANOLIS LIOGASTER* (Guerreran Anole). CANNIBALISM.** *Anolis liogaster* is a Mexican endemic (Muñoz-Alonso and Flores-Villela 1990. Cat. Amer. Amph. Rept. 489:1–2) and information on the natural history of this species is lacking. *Anolis* lizards have previously been reported to eat other lizards (Griffith and Wingate 1994. Herpetol. Rev. 25:26) but our observation reported herein is the first known record of cannibalism in *A. liogaster*, although this behavior has been reported in other members of the genus (Gerber 1999. *In* Losos and Leal [eds.], 1999. Anolis Newsletter V, pp. 28–39).

FIG. 1. Adult specimen of *Anolis liogaster* and a partially digested juvenile.

On 19 January 2014, in Chilpancingo, Guerrero, Mexico, we collected a male *A. liogaster* that had previously been captured by a Domestic Cat (*Felis catus*). We noticed the lizard specimen had a food bolus partially protruding from its mouth, which we identified as a partially digested juvenile of the same species (Fig. 1). We hypothesize that this behavior is a response to the disturbed, urban habitat or a consequence of high population density, resulting in the elimination of both natural predators and natural prey items.

The *Anolis liogaster* specimens were deposited in the Museo de Zoología Facultad de Ciencias as MZFC 28671 for the adult and MZFC 28672 for the juvenile prey item.

RICARDO PALACIOS-AGUILAR and **THALIA ELVIRA CRUZ-MACHUCA,** Facultad de Estudios Superiores Iztacala, Universidad Nacional Autónoma de México (UNAM), A. de los Barrios, CP 54090, Tlalnepantla de Baz, Estado de México, México (e-mail: ricardopalaciosaguilar@gmail.com).

***ANOLIS SAGREI* (Brown Anole). ABSCESS.** *Anolis sagrei* is native to Cuba, the Bahamas, and Jamaica, but has been introduced to many Caribbean countries and islands, including the Yucatán Peninsula where it is widespread in coastal areas (Lee 1996. The Amphibians and Reptiles of the Yucatán Peninsula. Cornell Univ. Press, Ithaca, New York. 500 pp.). Recently, it has been reported in the Banco Chinchorro Biosphere Reserve, an atoll located 31 km off the coast of the state of Quintana Roo, México (Charruau et al. Herpetol. Conserv. Biol., *in press*). During fieldwork on the reserve in April 2012, we captured five individual *A. sagrei* with deformations, abscesses, and swelling in their jaws, principally at the point of the mouth. We collected just one lizard (CNAR IBH 26868) for observations and determination of the nature of the wounds in laboratory. Two abscesses were removed via surgery and the lizard was maintained in a terrarium for 10 months, offered mealworms (*Tenebrio molitor*) and water *ad libitum*. Six months after the first surgery, the swelling came back at the same part of the jaw and we removed the tissue for analysis. We sent a swab from the tissue for bacterial culture and antibiogram; these laboratory tests obtained bacterial cultures of the genera *Streptococcus* and *Staphylococcus*, which are considered opportunistic pathogens (Huchzermeyer 2003. Crocodiles: Biology, Husbandry and Diseases. Onderstepoort Veterinary Institute, South Africa. 337 pp.). During the capture of *A. sagrei* we observed that

these lizards fed on the eggs of ants and in some cases the ants bit the lizards, principally in the mouth. We suggest that the wound caused by the ant bites could provoke the swelling and then infection leading to abscess. After eight months the lizard could not feed by itself and was fed manually.

***ANOLIS SAGREI* (Brown Anole). CANNIBALISM.** *Anolis sagrei* is native to the Bahamas and Cuba, but has been introduced to many tropical regions around the world (Kolbe et al. 2004. Nature 431:177–181). Although *A. sagrei* primarily eats invertebrates, it will sometimes consume other anoles (Losos 2009. Lizards in an Evolutionary Tree: Ecology and Adaptive Radiation of Anoles. University of California Press, Berkeley. 528 pp.). For example, adult *A. sagrei* are more likely to consume heterospecific juveniles than conspecifics given a choice (Gerber and Echternacht 2000. Oecologia 124:599–607). Nevertheless, cannibalism does occur in *A. sagrei* (Nicholson et al. 2000. Herpetol. Rev. 31:173–174), but in most other documented cases of *Anolis* cannibalism, the cannibalistic adult was a male rather than a female. Cannibalism by females is rare and has only been reported twice among anole species, once each in *A. cristatellus* and *A. whitemani*. One record was based on an autotomized tail found in stomach contents of a female, yet anoles will consume their own and others' shed tails (Gerber 1999. *In* Losos and Leal [eds.], 1999. Anolis Newsletter V, pp. 28–39). Additionally, a laboratory experiment demonstrated that adult female anoles ignore juveniles, whereas adult males attempt cannibalism more frequently (Stamps 1983. Behav. Ecol. Sociobiol. 12:19–33).

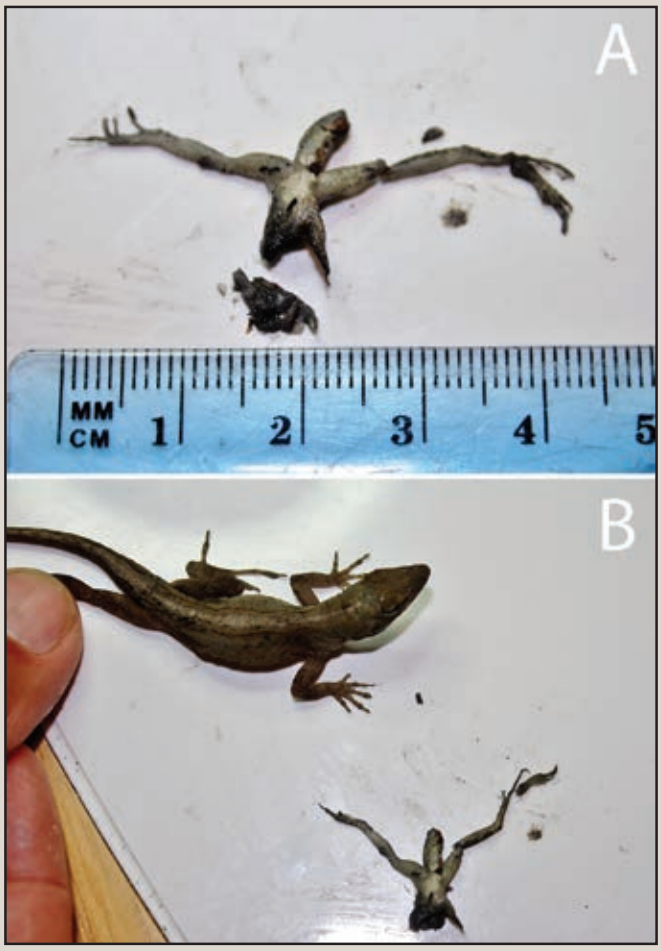

FIG. 1. Regurgitated carcass of a juvenile *Anolis sagrei* (A), and the cannibalistic adult female (B).

During our research on spoil islands in the Matanzas River near Palm Beach, Florida, USA (29.64°N, 81.21°W; WGS84), we collected an adult female *A. sagrei* that regurgitated a partially digested juvenile *A. sagrei* with only the posterior half of the abdomen, the hind legs, pelvic region, and partial tail remaining. The adult female was measured (mass = 2.63 g; SVL = 48 mm; TL = 78 mm) but the remnants of the carcass precluded accurate measurement of the cannibalized juvenile (Fig. 1). However, we identified the juvenile as female based on the absence of enlarged post-cloacal scales. To our knowledge, this is the first report of cannibalism by an adult female *A. sagrei*.

Past studies of *Anolis* suggest that competition is the primary selective force in island populations, whereas predation is more prominent in mainland populations (Calsbeek and Cox 2010. Nature 465[7298]:613–616). Depending on the frequency of cannibalism in *A. sagrei* populations, both forces may be at work because predation on young individuals by adults can influence future competition, and hence impact community structure and population dynamics (Gerber and Echternacht 2000. Oecologia 124:599–607). Thus, the role of cannibalism in driving ecological and evolutionary processes in *A. sagrei* may be particularly strong, and warrants more study.

***ANOLIS SAGREI* (Brown Anole). EGG PREDATION.** *Anolis sagrei* is native to many islands throughout the West Indies, and invasive populations have expanded throughout Florida primarily over the last half-century (Kolbe et al. 2004. Nature 431:177–181). Similar to other anoles, *A. sagrei* produces a single-egg clutch and oviposits at regular intervals (about every 7–10 days) throughout the reproductive season (Cox and Calsbeek 2010. Evolution 64[5]:1321–1330). At present, little is known about anole oviposition behaviors, but laboratory studies suggest that females choose oviposition sites with suitable conditions for embryo development (Socci et al. 2005. Herpetologica 61:233–240; Reedy et al. 2013. Behav. Ecol. 24:39–46). Although females tend to select sites with proper ambient conditions, some eggs still succumb to mortality. Predation could be a major factor driving variation in egg mortality in the field. For example, studies of *A. limifrons* demonstrate that leaf litter invertebrates (*Solenopsis* ants, *Salasiella* snails) contribute to egg mortality (Andrews 1982. Herpetologica 38:165–171; Chalcraft and Andrews 1999. Oecologia 119:285–292). Here, we report that marsh crabs may be another important predator of *Anolis* eggs.

FIG. 1. *Armases cinereum* with partially consumed anole egg.

While surveying populations of *Anolis sagrei* on spoil islands in the Matanzas River near Palm Beach, Florida, USA (29.64°N, 81.21°W; WGS 84) on 2 October 2013, we observed a Gray Marsh Crab (*Armases cinereum*) actively consuming an anole eggshell. The crab was measured (carapace length: 10 mm, carapace breadth: 1.2 mm, claw length: 8 mm) and photographed (Fig. 1). Gray Marsh Crabs are semi-terrestrial and found from high intertidal zones to 50 m inland. They have a broad distribution along the eastern coast of the United States, and into Veracruz, Mexico (Abele 1992. Smithson. Contrib. Zool. 527:30–31). Gray Marsh Crabs readily eat fresh plant material, carrion, and organic matter picked from sediments, but they also actively stalk small crustaceans and feed on soft-bodied invertebrates and small mollusks (Buck et al. 2003. J. Exp. Mar. Biol. Ecol. 292:103–116). Although we do not know if the crab killed the egg or if it was eating the eggshell after the hatchling emerged, this observation suggests that marsh crabs opportunistically eat anole eggs.

The spoil islands where we work have extremely high densities of Gray Marsh Crabs and fiddler crabs (*Uca* sp.). In addition, because of the high abundance of hatchling *A. sagrei* during late summer, we suspect that egg density at this time is also very high, allowing for crabs to come into contact with both incubating and hatched eggs. Indeed, crabs are often observed in the same microhabitats as anole eggs (Delaney et al. 2013. Herpetol. Rev. 44:314). The ability of *A. cinereum* to eat hard-shelled mollusks suggests that this species could also consume both intact and hatched anole eggs. Because *A. sagrei* lays eggs slightly below the surface of the ground in moist soil (unpubl. data), this oviposition location provides ample opportunity for interactions between eggs and marsh crabs. Although the observed eggshell being consumed could have been from *A. carolinensis*, it is more likely from *A. sagrei* given the substantially higher density of this species at our study site. Native *A. sagrei* populations are outside the geographic range of *A. cinereum*, but similar species of marsh crabs (genera *Sesarma* and *Armases*) in the Caribbean suggest that *Anolis* lizards and *Armases* crabs have probably had interactions over the course of their evolutionary history.

***ASPIDOSCELIS SEXLINEATA SEXLINEATA* (Six-lined Racerunner). SUPERNUMERARY CAUDAL ANOMALIES AND A BIFID TAIL.** We provide evidence that different types of wounds to the tail of an individual of *Aspidoscelis sexlineata sexlineata* can stimulate a range of responses including simple healing (i.e., closure of the wound), restoration (i.e., regeneration of the tail), development of a bifurcation (i.e., growth of a supernumerary second tail branch, Fig. 1A), or production of a cluster of supernumerary caudal extensions (i.e., growth of multiple tail branches, Fig. 1B–C). Consequently, this report expands the literature on caudal anomalies beyond references to tail bifurcation reported for an increasing number of lizard species (e.g., see Bateman and Chung-MacCoubrey 2013. Herpetol. Rev. 44:663; Vrcibradic and Niemeyer 2013. Herpetol. Rev. 44:510–511). The earliest report of a bifid tail in *A. sexlineata* known to us was published in Scientific American nearly 100 years ago (Anonymous 1915. Sci. Amer., p. 479)—that of a lizard from South Carolina. For a contemporary perspective, the examples of caudal anomalies in the three *A. sexlineata* from Alabama depicted in Fig. 1A–C are the only ones we have collectively observed in this species among several thousand specimens examined from Colorado, New Mexico, Texas, Kansas, Missouri, Louisiana, Arkansas, Oklahoma, Mississippi, Alabama, Georgia, Florida, South Carolina, and Tennessee. The recently published note (Cordes and Walker 2013. Herpetol. Rev. 44:319) on two triploid parthenogenetic *A. velox* from Utah are also the only other examples of bifid tails that can be recalled among the thousands of specimens of other species of *Aspidoscelis* examined by JMW.

From 1976–1979, SET studied the systematics (Trauth 1980. Ph.D. Dissertation, Auburn University) and natural history (Trauth 1983. Amer. Midl. Nat. 109:289–299) of *Aspidoscelis sexlineata* (= *Cnemidophorus sexlineatus*) across much of the southeast and south-central United States (Trauth and McAllister 1996. Cat. Amer. Amph. Rept. 628.1–628.12). In Alabama, only three of 201 specimens of *A. s. sexlineata* examined by SET expressed caudal anomalies other than simple tail regeneration. Two of them exhibited multiple fractures and subsequent growths of supernumerary tails (Fig. 1A–C). The phenotypically altered lizards (SET 2333; Auburn University Museum = AUM 27525; SET 2313) were collected from three south-central counties (Autauga, 32.70166°N, 86.48889°W; Chambers, 32.89288°N, 85.23701°W; Elmore, 32.57513°N, 85.94301°W, respectively). Each lizard was excavated from either activity or hibernation burrows in mostly well-drained red clay exposures, which faced S to W along secondary highways or rural dirt roads.

In SET 2333 (male, 64 mm SVL), the bifurcation developed immediately distal to the ~43rd whorl of caudal scales as the probable result of a moderately severe injury, leaving the original tail capable of growth and with an essentially anatomically normal appearance. The resulting supernumerary tail is almost as long as the original and possesses the types of scales typical of a regenerated portion of a tail (Fig. 1A). The result is what we term the classical bifid tail. In AUM 27525 (male, 74 mm SVL), the supernumerary aggregate of caudal extensions developed as a trifurcation immediately distal to the ~57th whorl of caudal scales as the probable result of multiple wounds, leaving the original tail incapable of normal growth and anatomically abnormal in appearance. A few mm distal to the trifurcation, the original tail has a bifurcation (Fig. 1B), the whole array being what we term supernumerary caudal extensions. In SET 2313 (female, 75 mm SVL), a trifurcation has developed immediately distal to the ~52nd whorl of caudal scales as the probable result of a complex wound, leaving the original tail incapable of normal growth and anatomically

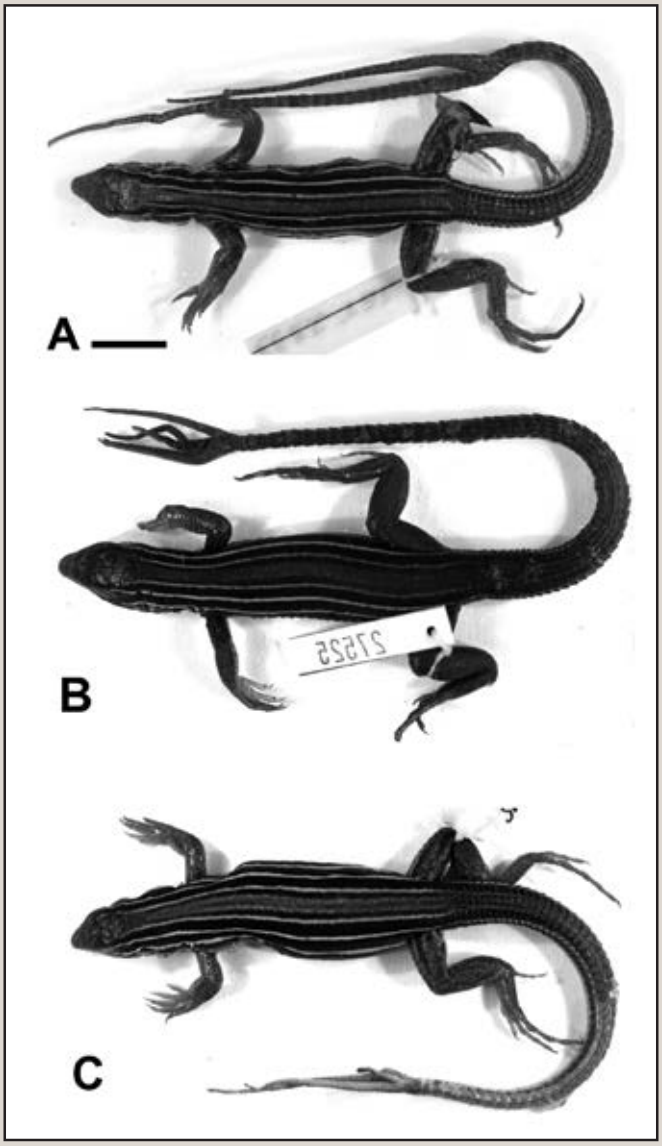

FIG. 1. Specimens of *Aspidoscelis sexlineata sexlineata* from three Alabama counties expressing bifid and multiple supernumerary tails. A) SET 2333; line = 10 mm for A–C. B) AUM 27525. C) SET 2313.

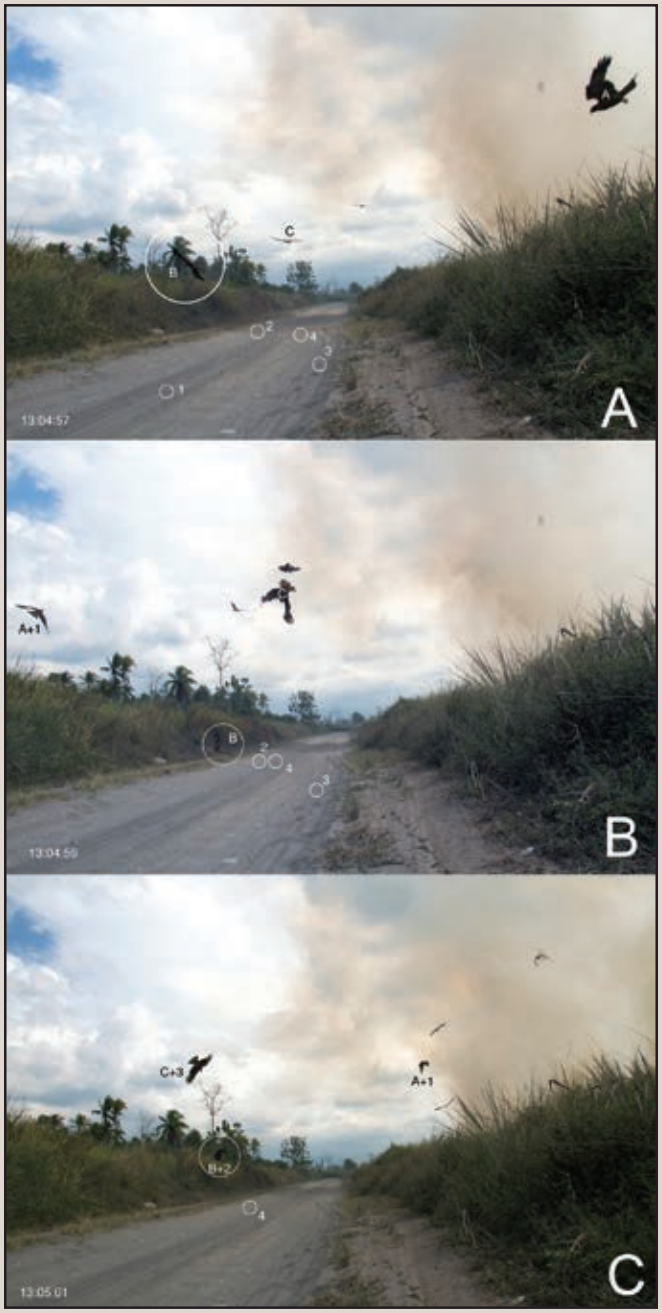

FIG. 1. A) 13:04:57 Hawk A stoops on Skink 1, Hawk B wheels towards Skink 2. B) 13:04:59 Hawk A has taken Skink 1; Hawk B is almost upon Skink 2; Hawk C, approaching from down the road, wheeling to stoop on Skink 3. C) 13:05:01 Hawks A, B and C have all taken skinks, only Skink 4 remains.

abnormal in appearance. The result in this lizard is a trifurcation that has produced a cluster of three supernumerary caudal extensions (Fig. 1C). We conclude that caudal autotomy and regeneration in whiptail lizards are examples of adaptive responses that are stimulated by a traumatic event, the nature of which on rare occasions results in production of non-adaptive structures (i.e., growth of supernumerary caudal extensions).

***CARLIA CURTA* (Papuan Litter Skink) and *CARLIA MYSI* (Mys' Rainbow Skink). MASS AVIAN PREDATION.** *Carlia curta* and *C. mysi* are common lizards of the grasslands of the northern versant of the Papuan Peninsula, Papua New Guinea, and they occur in abundance on the disused Second World War airstrip at Dobudora, Oro (Northern) Province, Papua New Guinea (8.793950°S, 148.320333°E) located 9.5 km ESE of the provincial capital Popondetta, and 2 km NE of the domestic airport at Girua, on the eastern banks of the Girua River.

The area is low-lying (40–80 m elev.) and largely comprises grassland, swamp, small areas of tropical forest, and oil palm plantations. The grasslands are subjected to frequent and deliberate burns, set by villagers, whether clearing land for gardens, or hunting bandicoots, and fire is an ever-present factor in the

environment. During the present (August 2013) and previous (September 2006) visits to Dobudora there have always been two or three fast-burning fires on the grasslands. Wildlife has to adapt to the constant threat it poses.

Some wildlife benefit from these continual, dry-season daily, grassland fires. Birds of prey, primarily Black Kites (*Milvus migrans*), were seen in very large numbers in the vicinity of Dobudora in August 2013, congregating on trees in close proximity to the fires, or following behind the flames scavenging carcasses. Twenty were seen at any one time wheeling in the sky, up to 12 perching in a single, spindly leafless tree.

Even before the flames reached the dirt road, both species of skinks were observed running out onto its exposed sandy surface, clearly disorientated by the heat, some making the safety of the opposite side of the road, others running in circles, or even back towards the fire. At this point the kites were observed to change their hunting behavior and began predating the skinks in the open. At least a dozen kites were hunting in less than 50 m of the road, swooping down to capture disoriented skinks in their talons. Occasionally a skink was missed but flicked over in the sand, only to be almost immediately taken by a second kite coming in at an angle to the first. Our attempts to collect skinks as voucher specimens were on occasion thwarted as the lizards were snatched from in front of our hands by kites from above. No estimate of the number of skinks taken by the kites was made, or even possible due to the speed and numbers of the birds, but it was probably several dozen during the 30–40 minutes between the skinks' first appearance on the road and the fire dying down. How the number of skinks taken fleeing can be compared to those that die in the fires is also impossible to estimate but with the frequency of fires on the grasslands and the large number of kites in the vicinity it is likely that these two threats play a major part in skink survivorship and population density.

We noticed that the larger species, *C. mysi*, was more vulnerable to predation by kites than the smaller *C. curta*, many of which escaped the notice of the birds in the dusty sand and smoke. One snake was observed, either a treesnake (*Dendrelaphis* sp.) or Brownsnake (*Pseudonaja textilis*), but it crossed the road too quickly for the kites or us to react.

A sequence of three photographs, taken over a four-second period, show four *C. mysi* attempting to cross the road (Fig. 1). Skink 1 is taken by Hawk A which dives from the right, Skink 2 is taken when Hawk B comes in low from in front of camera, Hawk C flies up the road towards the camera then swoops onto Skink 3. At the end of four seconds only Skink 4 remained.

We thank New Britain Palm Oil Ltd. for facilitating our visit to Oro Province, by providing accommodation, food, and transportation, and Hayward Korina, our driver during our stay. MO thanks David Williams and the Australian Venom Research Unit/Charles Campbell Toxinology Centre, Port Moresby, for arranging his return to PNG and providing accommodation and transportation in Port Moresby.

***CARLIA SCHMELTZII* (Robust Rainbow Skink). ENVIRONMENTALLY-CUED HATCHING.** Environmentally-cued hatching (ECH), in which hatching competent embryos can choose their own hatching date by assessing and responding to risks, can include early hatching, delayed hatching, or synchronous hatching (Warkentin and Caldwell 2009. *In* Dukas and Ratcliffe [eds.], Cognitive Ecology II. The Evolutionary Ecology of Learning, Memory and Information Use, pp. 177–200. University of Chicago Press, Chicago, Illinois). For example, hatching competent frog embryos can hatch early in response to risk of attacks by wasps, snakes, and fungi (Warkentin and Caldwell, *op. cit.*). A recent review has extended ECH to reptiles (Doody 2012. Integr. Comp. Biol. 51:49–61). For instance, early hatching in Delicate Skinks (*Lampropholis delicata*) is likely an antipredator response to egg predation (Doody and Paull 2013. Copeia 2013:160–165). Although a few other lizard species can hatch early in response to being handled, ECH is not known to occur for most lizard species, presumably due to the difficulty in finding lizard eggs (Doody et al. 2009. Quart. Rev. Biol. 84:229–252) and due to the common assumption that eggs hatching while being handled is coincidental. Herein we report on an observation of early hatching in *Carlia schmeltzii* from northeastern Australia. We comment on implications for predator avoidance.

In January 2014 at around 1200 h a maintenance worker discovered two eggs under a rock in a garden in Palm Cove, Queensland, Australia (16.744307°S, 145.670962°E). The worker placed the eggs in a container, and the eggs were rolling around during transit for a few minutes before being presented to one of us (BS). Just after this time one of the eggs hatched rapidly, and the hatchling skink immediately scurried around the container. The second egg was then removed and hatched rapidly in hand, the hatchling immediately running after hatching. The hatchlings were identified as *C. schmeltzii* based upon their appearance and commonness at the site.

The handling-induced hatching in *C. schmeltzii* likely reflects early hatching in response to an increase in perceived predation risk, as observed in two other Australian skinks, *L. delicata* and *Acritoscincus platynota* (Doody and Paull, *op. cit.*; BS, unpubl.). Early hatching in response to predation risk may be widespread in Australian skinks, or perhaps in skinks in general. Further research should investigate the hatching window (plasticity in hatching age and developmental stage) and the potential predators of *C. schmeltzii*. A comparative study of ECH in skinks would determine if early hatching is an ancestral trait or if it has evolved multiple times within that group.

***CTENOPHORUS CAUDICINCTUS* (Ring-tailed Dragon). PREDATION.** Clarifying the suite of predators can contribute to understanding how populations are regulated, and how predators influence the behavior of prey. Yet, the suite of predators is often poorly known for a given small vertebrate, especially in the tropics. Herein we report an observation of apparent predation of *Ctenophorus caudicinctus* by a Nankeen Kestrel (*Falco cenchroides*) in northwestern Australia.

At ~1100 h on 22 February 2014, we flushed a kestrel from a rocky overhang on a mesa that stood about 50 m above the surrounding savannah in the northern Pilbara region of Western Australia (22.337336°S, 119.625572°E). The kestrel left behind an upside-down dead lizard, which proved to be a gravid female *C. caudicinctus*. Closer inspection revealed two puncture marks, one each through the left shoulder region and through the right

tympanum, although there was little blood. The lizard was left at the site in case the kestrel returned for it. The air temperature at the time of the observation was ~35°C.

Although we did not observe prey capture, kestrels are generally hunters rather than scavengers (Olsen et al. 1979. Emu 79:133–138), suggesting that the raptor caught and killed the lizard just before we arrived (the lizard was in good condition). It is possible that the reproductive condition of the lizard contributed to its vulnerability to capture, as it was heavily egg-laden. Ring-tailed Dragons are common at the site, and are generally common in rocky areas where they forage for insects during the day, often at very hot temperatures. Kestrels are also relatively common at the site, and lizards are generally an important prey item; in one study lizards made up ~90% of prey items by weight (Aumann 2001. Wildl. Res. 28:379–393). In that study agamids were found in 53% of regurgitated pellets, and *C. nuchalis*, a congener of *C. caudicinctus*, was the most common reptilian prey item.

***DAREVSKIA BRAUNERI* (Brauner's Rock Lizard). DIET.** The diet of *Darevskia brauneri* is known to consist mainly of insects, other invertebrates, berries, and overripe fruit (Darevsky 1967. Rock Lizards of the Caucasus: Systematics, Ecology and Phylogeny of the Polymorphic Groups of Caucasian Rock Lizards of the Subgenus *Archaeolacerta*. Nauka, Leningrad. 214 pp. [in Russian: English translation published by the Indian National Scientific Documentation Centre, New Delhi, 1978]). However, on 28 August 2001 on rocky outcrops of the valley of the Mzymta River in the village of Esto-Sadok, Krasnodar Krai, Russia (43.68093°N 40.27605°E; 550 m elev.) we observed an adult female holding a juvenile specimen of *Lacerta agilis* (Sand Lizard) in its jaws. This is the first recorded case of a lizard of the genus *Darevskia* predating on a vertebrate. An earlier report in the literature recorded the opposite case of *L. agilis* predating upon a lizard of the genus *Darevskia* (*D. pontica*) (Zhukov 1941. K sistematike, rasprostraneniyu i biologii *Lacerta praticola* Eversmann [Reptilia, Sauria] [Systematic, distribution and biology of *Lacerta praticola* Eversmann (Reptilia, Sauria)]. Proc. Krasnodar State Pedagogical Institute named after the 15th anniversary of the Komsomol. Krasnodar. Vol. 8. pp. 326–335 [in Russian]).

DORONIN**, Department of Herpetology, Zoological institute of Russian Academy of Sciences, St. Petersburg 199034, Russia (e-mail: ivdoronin@mail.ru)

***ELGARIA PAUCICARINATA* (San Lucan Alligator Lizard). FIELD AND PREFERRED BODY TEMPERATURES.** *Elgaria paucicarinata* is a small terrestrial lizard endemic to the mountain and foothill habitats of the Cape Region in Baja California (Grismer 2002. Amphibians and Reptiles of Baja California, Including its Pacific Islands and the Islands in the Sea of Cortés. Univ. California Press, Berkeley and Los Angeles, California. 399 pp.). Little is known about the ecology of this lizard, and even less about the thermal ecology. We present data on *E. paucicarinata* thermal ecology from Sierra de La Laguna Biosphere Reserve on the Cape Region, Baja California Sur, México. We conducted fieldwork at Segundo Valle (23.55251°N, 109.98689°W, WGS84; elev. 1770 m) on 12–14 July and 20–22 September 2011. The site is predominated by pine-oak forest vegetation (e.g., *Pinus lagunae*, *Quercus devia, Arbutus peninsularis*), perennial herbs, leaf litter, and granitic rocks (Arriaga and Ortega [eds.] 1988. La Sierra de la Laguna de Baja California Sur. CIBNOR. Mexico. 247 pp.). Data are based on 20 individuals (adults and juveniles) captured by hand between 0900 and 1900 h. Sex was not determined because of the lack of sexually dimorphic characters. We measured body temperature (T_b) and air temperature (T_a) with a quick-reading thermometer (Fluke 52 K/J type) immediately following capture. The substrate temperature (T_s) was measured with a non-contact infrared thermometer (Raytek Raynger ST®) at the exact point where the animal was first sighted and T_a 2 cm above the substrate. We recorded data on snout–vent length (SVL), time of capture, microhabitat type, and light condition (full sunlight, filtered sunlight, and full shade). We brought five adult individuals into a laboratory thermal gradient to measure the preferred body temperatures (T_p). The thermal gradient consisted of a glass terrarium 76 × 30 × 45 cm (long/wide/high), with soil and leaf litter, located in a room with a controlled temperature of 20°C. We offered a thermal gradient of 20–37°C by placing two 100-W daylight blue bulbs at different heights in one end of the terrarium. We took body temperatures every hour between 0900 and 1500 h, with the same thermometer used in the field.

Mean SVL was 96.8 mm (SD = 20.6, range: 58–120 mm, N = 12). Mean field T_b was 25.4°C (SD = 3.2, range: 20–31.2°C, N = 20). Mean T_a was 20.8°C (SD = 1.5, range: 17.5–24.1°C) and mean T_s was 24°C (SD = 3.6, range: 19.2–31.8°C). Both T_a and T_s were significantly correlated with body temperature (Spearman Rank Correlation, $r_s = 0.80$, $r_s = 0.84$, $P < 0.0001$, respectively). Most lizards were found on leaf litter with plant cover (N = 13), followed by leaf litter on open areas (N = 5), oak logs, and rocks (N = 1); and in full shade microhabitats (N = 11), followed by full sunlight (N = 6) and filtered sunlight (N = 3). The mean T_p was 25.8°C (SD = 3.4, range = 20.5–30.9°C). Interquartile of 25% and 75% was 24.6°C and 27.9°C, respectively. *E. paucicarinata* mean body temperature is higher than other *Elgaria* species (*E. coerulea* = 15.8°C, Brattstrom 1965. Am. Midl. Nat. 73[2]:376–422; *E. multicarinata* = 21°C, Beck 2009. *In* Jones and Lovich [eds.], Lizards of the American Southwest, pp. 484–487. Rio Nuevo Publishers, Tucson, Arizona). Compared with other gerrhonotine lizards, *E. paucicarinata* has a slightly lower T_b than *Barisia imbricata* (26.6°C; Lemos-Espinal et al. 1998. Amphibia-Reptilia 19:95–99). The positive correlation of T_b with T_s and T_a suggests that *E. paucicarinata* is not clearly thigmothermic or heliothermic. Light condition preference data give support to a thigmothermic model where lizards gain heat by moving between microhabitats with different sunlight categories, because lizards were found in open and plant-covered areas. The similarity of T_p and field T_b suggests that *E. paucicarinata* thermoregulates, but an assessment of the thermal environment is needed to determinate the patterns of thermoregulation of this species.

We thank Anny Peralta-García for comments on the manuscript, and Abelino Cota and Franco Cota for their help during fieldwork.

***GEHYRA LACERATA* (Kanchanaburi Four-clawed Gecko). REPRODUCTION.** *Gehyra lacerata* is known from Chonburi, Kanchanaburi, Khon Kaen, Nakhon Ratchasima, Phetchaburi and Sakaeo Provinces, Thailand and possibly Vietnam (Das 2010. A Field Guide to the Reptiles of South-east Asia: Myanmar, Thailand, Laos, Cambodia, Vietnam, Peninsular Malaysia, Singapore, Sumatra, Borneo, Java, Bali, New Holland Publishers, London, UK. 376 pp.). I know of no published accounts on reproduction of this lizard. The purpose of this note is to report on reproduction of *G. lacerata* from Thailand.

A sample of 24 *G. lacerata* consisting of 11 adult males (mean SVL = 47.1 mm ± 4.1 SD, range = 40–53 mm) and 13 adult females (mean SVL = 53.2 mm ± 5.7 SD, range = 43–59 mm) collected in 1969 and deposited in the herpetology collection of the Field Museum of Natural History (FMNH), Chicago, Illinois, USA, was examined from Thailand (Nakhon Ratchasima Province, Amphoe Pak Thong Chai, Sakerat, 14.50897°N, 101.95379°E, including: FMNH 181335, 181338–181340, 181342, 181347, 181348, 181350, 181352–181354, 181360, 181364, 181367, 181370–181372, 181388, 181393, 181407, 181411, 181414, 181418, 181421.

A cut was made in the lower abdominal cavity and the left testis or ovary was removed, embedded in paraffin, cut at 5 µm and stained with Harris hematoxylin followed by eosin counterstain. Enlarged ovarian follicles > 4 mm or oviductal eggs were counted. No histology was performed on them. Histology slides were deposited at FMNH.

The only stage observed in the testicular cycle was spermiogenesis. There were two stages of this condition: 1) full spermiogenesis in which the layers of germinal epithelium were at maximum cell number and the lumina of the seminiferous tubules were lined by sperm or clusters of metamorphosing spermatids; 2) late spermiogenesis in which the cells of the germinal epithelium were greatly reduced in number and scattered sperm were in the lumina of the markedly smaller seminiferous tubules. Males in full spermiogenesis were found by month: February (N = 1), March (N = 1), April (N = 2), June (N = 1), August (N = 1), November (N = 1), December (N = 2). Two males from September exhibited late spermiogenesis. My monthly samples of males are too small to ascertain whether the finding of late spermiogenesis in September precedes a period of testicular regression. However, my November and December male samples exhibited full spermiogenesis. The smallest reproductively active male measured 40 mm SVL and was from December (FMNH 181414).

TABLE 1. Monthly stages in the ovarian cycle of 13 *Gehyra lacerata* females from Nakhon Ratchasima Province, Thailand. *Indicates concurrent yolk deposition for a subsequent clutch in a female with oviductal eggs.

Month	N	Quiescent	Follicles > 4 mm	Oviductal eggs
February	2	0	1	1
March	2	0	2	0
April	1	0	0	1
May	1	0	1	0
June	1	0	0	1*
July	3	0	2	1*
August	1	1	0	0
September	1	1	0	0
November	1	1	0	0

Three stages were present in the ovarian cycle (Table 1): 1) quiescent = no yolk deposition; 2) enlarged ovarian follicles (> 4 mm); 3) oviductal eggs. Mean clutch size (N = 10) was an invariant two eggs. The smallest reproductively active female (two ovarian follicles) measured 50 mm SVL and was from March (FMNH 181353). I arbitrarily classified one slightly smaller female of 47 mm SVL (FMNH 181393) and two females of 43 mm SVL (FMNH 181411, 181339) as adults, although they could have conceivably been subadults. The presence of two females (FMNH 181364, 181372) with oviductal eggs that were undergoing concurrent yolk deposition for a subsequent clutch indicates *G. lacerata* can produce multiple clutches in the same reproductive season.

It is evident that *G. lacerata* exhibits a prolonged reproductive cycle. Examination of additional specimens will be required to ascertain whether breeding occurs year round as postulated for other lizards from south Asia (Grismer 2011. Lizards of Peninsular Malaysia, Singapore and their Adjacent Archipelagos. Edition Chimaira, Frankfurt am Main. 728 pp.).

I thank Alan Resetar (FMNH) for permission to examine *G. lacerata*.

***GEKKO JAPONICUS* (Japanese Gecko). DIURNAL ACTIVITY.** Nocturnal behavior and thermoregulation in *Gekko japonicus* has been described in a number of works but detailed documentation of diurnal behavior is lacking (Hu and Du 2007. Acta Zoo. Sinica. 53:227–232 [in Chinese]). Here I describe diurnal activity by *G. japonicus* based on 69 observations documented at three sites in Fukuoka, Japan (Table 1). Observations took place between 23 July 2011 and 29 October 2013, occurring as early as March and as late as October. All observations occurred between 0909 h and 1745 h. Temperatures during observations ranged from 17°C to 33.9°C, with an average of 24.7°C. Diurnal behavior was most frequently observed in sunny weather, with 50.7% (N = 35) of observations occurring under mostly clear or clear skies, 30.4% (N = 21) taking place in partly cloudy weather, and 18.8% (N = 13) occurring during overcast conditions.

With the exception of one gecko seen on a stone wall, diurnal activity by *G. japonicus* was observed at retaining walls with weep holes (59.4%, N = 41), on trees (29.0%, N = 20), or on wooden signposts (10.1%, N = 7). In most instances, the geckos would almost immediately retreat into their refuge when approached. In 91.3% (N = 63) of the observations, the geckos were positioned at their refuges in one of three ways: At the entrance of the refuge at the edge of direct sunlight and shadow (40.6%, N = 28); at the refuge entrance with anterior portion of the body or head exposed to direct sunlight (37.7%, N = 26); or completely exposed outside of refuge but immediately next to the entrance (13%, N = 9). In 8.7% (N = 6) of the instances the geckos were completely exposed on a wall or the shaded side of a tree trunk with no refuge in the immediate vicinity. Body posture varied from having the ventral surface in contact with substrate to having the anterior portion of the body elevated as high as possible.

In seven instances, aggregations of two to four animals were observed at refuge entrances. All but one of these observations occurred in the months of March and April. Based on prior observations, it is known that an aggregation seen at a weep hole on 27 April 2012 had overwintered together and was in the process of gradually dispersing (Caldwell 2013. Herpetol. Rev. 44:4) and a group of four geckos observed at a signpost on 15 April 2012 is

NR = Completely outside refuge immediately next to entrance
TE = On tree trunk or wall near no immediate refuge

also known to have overwintered together. In all other instances, single animals were observed.

In five instances I was able to observe geckos at weep holes for extended periods of time, ranging from 15 to 60 minutes from 3–5 m away. All geckos demonstrated the same behavior; each would expose its head or anterior half to direct sunlight, retreat into the hole when a pedestrian or potential predator (e.g., a dog or a bird) would approach, and subsequently return to the same position within ten minutes. The only other movement type observed was changes in body posture. No incidents of predation by or on the geckos were observed.

Gekko japonicus is reported to primarily be a sit-and-wait predator (Werner et al. 1997. Asiatic Herpetol. Res. 7:153–165), and foraging cannot be ruled out here. However, many of these observations, particularly instances in which the geckos in refugia expose the anterior portions of their bodies to direct sunlight and/or exhibit postural changes, are indicative of thermogulatory behavior. Though it is not widely documented, diurnal thermoregulation probably occurs in a large number of nocturnal reptiles (Kearney and Predavec 2000. Ecol. 81:2984–2996). *Christinus marmoratus*, a nocturnal gecko species, is reported to engage in diurnal thermoregulation largely through refuge selection and postural variation (Kearney and Predavec 2000, *op. cit.*) and a study by Dial (1978. Herpetologica 34:191–201) indicated that *Coleonyx brevis*, another nocturnal gecko, actively engages in diurnal thermoregulation while under cover. Much of the activity reported here suggests diurnal thermoregulatory behavior occurs in *G. japonicus* as well.

I thank Xi Hong for assisting with English translations of Chinese literature cited.

KENT R. CALDWELL, 1-22-8 205 Yoshizuka, Hakata-ku, Fukuoka-shi, Fukuoka-ken, 812-0041 Japan; e-mail: Allosaurus.fragilis@gmail.com.

***GONATODES HUMERALIS* (Trinidad Gecko). PREDATION.** *Gonatodes humeralis* is a small (max. SVL = 42 mm) sphaerodactylid gecko, common throughout much of the Amazonian region, present both in rainforest and in disturbed habitats like secondary forest and urban parks with trees (Ávila-Pires et al. 2011. Herpetol. Brasil. 1:111–112). It is typically found on tree trunks up to 1.5 m above the ground, but it also occurs in leaf litter and higher up within trees (Ávila-Pires 1995. Zool. Verh. Leiden 299:1–706). This note reports a single observation of predation on *G. humeralis* by a Spotted Puffbird (*Bucco tamatia*).

On 13 March 2012 at 1647 h during fieldwork at Curiau Protection Area (0.238056°N, 51.129444°W; datum WGS84), Macapa, Amapa, northern Brazil, we observed an adult Spotted Puffbird predating an adult female *G. humeralis* (SVL = 35 mm). The puffbird was perched on a tree branch, staring at the trunk of the tree. After locating the gecko, the bird flew to the trunk and captured it, returning to the canopy soon after, with the gecko on

PHOTO BY K.M.O. AGUIAR

FIG. 1. A Spotted Puffbird (*Bucco tamatia*) preying on an adult female *Gonatodes humeralis* in Curiau Protection Area, Macapa, Amapa, North Brazil.

its beak (Fig. 1). The bird then began to beat the gecko against the tree branch, killing it shortly thereafter. The Spotted Puffbird is a insectivorous and frugivorous bird (Sigrist 2013. Avifauna Brasileira. Editora Avisbrasilis. 594 pp.). This is another record of a sphaerodactylid gecko in the diet of *B. tamatia*, and the first record of *G. humeralis* predation by this species.

KURAZO M. OKADA AGUIAR, Bio-Ornithos Consultoria Ambiental, Macapá, AP, Brazil (e-mail: kurazookada@hotmail.com); **CARLOS E. COSTA-CAMPOS**, Universidade Federal do Amapá, Departamento de Ciências Biológicas e da Saúde, Laboratório de Herpetologia, Campus Marco Zero, 68903-419, Macapá, AP, Brazil (e-mail: eduardocampos@unifap.br).

***GYMNODACTYLUS GECKOIDES* (Naked-toed Gecko, Lagartixa). HATCHLING SIZE/BEHAVIOR.** *Gymnodactylus geckoides* is endemic to Caatinga in northeastern Brazil (Cassimiro and Rodrigues 2009. Zootaxa 2008:38–52). Females appear to produce eggs continuously throughout the year (Vitt 1986. Copeia 1986:773–786) and clutch size is usually comprised of one egg (rarely two) with a calcareous shell, which is deposited under rocks or in hollow fallen logs (Vanzolini et al. 1980. Répteis das Caatingas. Academia Brasileira de Ciências, Rio de Janeiro. 161 pp.; Vitt 1986, *op. cit.*; Vitt 1995. Occ. Pap. Oklahoma Mus. Nat. Hist. 1:1–129).

On 9 October 2013 we collected one adult and one juvenile of *G. geckoides* from Brumado, Bahia state, Brazil, located within Caatinga domain (14.203889°S, 41.665278°W; 422 m elev.). We measured the two lizards with a digital caliper (± 0.01 mm) for snout–vent length (SVL) and tail length (TL). The juvenile had

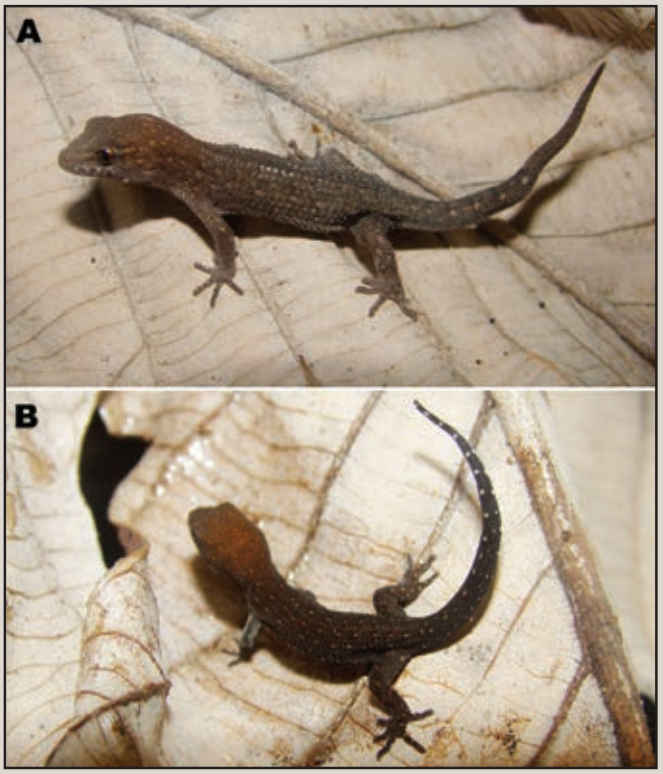

FIG. 1. A) An adult individual of *Gymnodactylus geckoides* (UFMG 1908) and B) a juvenile individual of *G. geckoides* (UFMG 1909) showing defensive tail display.

SVL = 19.41 mm and TL = 20.59 mm, and the adult had SVL = 35.22 and TL = 35.0 mm. It is believed that the juvenile was a recent hatchling due to its smaller size than the minimum SVL reported by Vitt (1986, *op. cit.*) (SVL = 20 mm) in Exu city, Pernambuco state, Brazil. The specimen here reported, probably a recent post-hatchling, represents a new record for minimum body size for a *G. geckoides* juvenile.

A defensive tail display was made by both lizards (Figs. 1A, B), and this behavior apparently is common in some Brazilian geckos (Colli et al. 2003. J. Herpetol. 37:694–706; Brandão and Motta 2005. Phyllomedusa 4:139–145), but it has not been reported for this species. It is evidence for possible mimicry of scorpions, as they use the same microhabitats, are exposed to the same potential predators, and present similar behaviors when threatened (Brandão and Motta 2005, *op. cit.*). There is little published information about the life history and behavior of this species; this report adds to the knowledge of these phyllodactylid lizards from Brazil.

The *G. geckoides* specimens (UFMG 1908–1909) were deposited in the Herpetological Collection of Universidade Federal de Minas Gerais. We are grateful to CAPES for doctorate fellowships awarded to SCG.

Antônio Carlos, 6627, CEP: 31270-901, Belo Horizonte, MG, Brazil.

***HEMIDACTYLUS FRENATUS* (Common House Gecko). BICEPHALY.** *Hemidactylus frenatus* is a small gecko species distributed primarily in Southeast Asia (Das 2010. A Field Guide

FIG. 1. Photo of bicephalic *Hemidactylus frenatus* from Koror, Palau.

to the Reptiles of South-east Asia. New Holland Publishers, London. 376 pp.). Individuals are common in urban or otherwise disturbed areas. On 8 February 2014, SK observed a small shedding *H. frenatus* fall from the ceiling of a residence in Koror, Palau (7.342°N, 134.478°E). Upon examination the lizard was found to be bicephalic (Fig. 1), with two heads joined medially directly posterior to the eyes. This abnormality is likely either parapagus, a fusion of two individuals referred to as conjoined twins, or diprosopus, a duplication of facial tissues on the head commonly called craniofacial duplication. The animal appeared healthy and alert, moving with the rapidity found in unaffected individuals. All four eyes appeared to be functional, as did both mouths, but prey capture and handling was not observed. To our knowledge, this is the first published case of bicephaly in this species. The gecko was unharmed and released outside near the point of capture.

McKELVY, Department of Biology, The Graduate School, City University of New York, New York, New York 10016, USA; and Department of Biology, 6S-143, College of Staten Island, 2800 Victory Blvd., Staten Island, New York 10314, USA (e-mail: amckelvy@gc.cuny.edu); **STORM KOSHIBA,** Koror, Palau (e-mail: stormkosh@gmail.com).

***HEMIPHYLLODACTYLUS TITIWANGSAENSIS* (Titiwangsa Slender Gecko). REPRODUCTION.** *Hemiphyllodactylus titiwangsaensis* is restricted to the Malaysian state of Pahang (Grismer 2011. Lizards of Peninsular Malaysia, Singapore and their Adjacent Archipelagos. Edition Chimaira, Frankfurt am Main. 728 pp.). Grismer (2011, *op. cit*) reported gravid females carrying two eggs during March, May, July, August and October and postulated breeding occurred throughout the year. The purpose of this note is to add information on the reproductive cycle of *H. titiwangsaensis* from a histological examination of museum specimens.

A sample of ten *H. titiwangsaensis* from Cameron Highlands, Panang state, West Malaysia collected during 2005, 2008, 2010, 2011 and deposited in the herpetology collection of La Sierra University (LSUHC), Riverside, California was examined: LSUHC 7208, 7209, 7212, 7213, 9161, 9162, 9076, 9815, 10254, 10273. The sample consisted of eight females (mean SVL = 52.1 mm ± 2.4 SD, range = 48–55 mm), one male, SVL = 58 mm and one subadult, SVL = 38 mm.

TABLE 1. Stages in the ovarian cycle of eight *Hemiphyllodactylus titiwangsaensis* from Cameron Highlands, Panang State, Malaysia.

Month	N	Quiescent	Enlarged follicles > 4 mm	Oviductal eggs
March	3	0	2	1
June	1	1	0	0
August	2	1	1	0
September	1	1	0	0
November	1	0	0	1

A cut was made in the lower abdominal cavity and the left testis or ovary was removed, embedded in paraffin, cut into sections and stained with Harris hematoxylin followed by eosin counterstain. Enlarged follicles (> 4 mm) or oviductal eggs were counted. Histology slides are deposited at LSUHC.

The one male examined was from March and was undergoing spermiogenesis (lumina of the seminiferous tubules were lined by sperm or clusters of metamorphosing spermatids).

Three stages were found in the ovarian cycle (Table 1): 1) quiescent, no yolk deposition; 2) enlarged ovarian follicles > 4 mm; 3) oviductal eggs. Mean clutch size for five females = 1.8 ± 0.45 SD, range = 1–2. Reproductive activity at opposite ends of the year indicates *H. titiwangsaensis* has an extended reproductive cycle as postulated by Grismer (2011, *op. cit.*). Congeners of the parthenogenetic *H. typus* from Hawaii similarly underwent an extended period of reproduction as they exhibited reproductive activity in seven of nine months examined (Goldberg 2012. Gekko 6:23–25).

***HOLBROOKIA LACERATA SUBCAUDALIS* (Southern Spot-tailed Earless Lizard). REFUGIA AND COMMENSALISM.** The use of ground squirrel and other mammal burrows by many species of lizards has been well-documented. Among those reports: juvenile *Uta stansburiana* (Side-blotched Lizard) in central California stayed in the burrows of *Otospermophilus beecheyi* (California Ground Squirrel) from July to November (Doughty and Sinervo 1994. J. Herpetol. 28:485–490); burrows of *Ictidomys mexicanus* (Mexican Ground Squirrel) are sometimes used by *Holbrookia propinqua* (Keeled Earless Lizard) to escape predation (Cooper 2000. Behaviour. 137:1299–1315); and a positive correlation was found between the number of prairie dog burrows and abundance of *H. maculata* (Lesser Earless Lizard; Davis and Theimer 2003. Amer. Midl. Nat. 150:282–290).

Knowledge of the life history requirements and population dynamics of the rare and elusive *H. l. subcaudalis* is extremely limited. Nearly everything that has been reported on its natural history, from direct observation, comes from the 1950s research of Ralph Axtell, who described two subspecies, *H. l. lacerata* (Northern Spot-tailed Earless Lizard) and *H. l. subcaudalis* (Axtell 1956. Bull. Chicago Acad. Sci. 10[11]:163–179). Axtell reported that *H. l. lacerata* will use tall grass and cracks in the earth

as escape shelters, but that "rocks, tin, boards, etc., are never used..." (Axtell 1954. MS Thesis. Univ. of Texas at Austin). Axtell also reported on the use of mammal burrows by other members of the genus (Axtell 1958. Ph.D. Dissertation. Univ. of Texas at Austin.) but never observed that behavior in *H. l. subcaudalis* (R. Axtell, pers. comm.). This is the first report of the use of ground squirrel or any other type of burrows by *H. l. subcaudalis*. In this note we present evidence that *H. l. subcaudalis* not only uses ground squirrel burrows, but that it is dependent on them at this site.

On 18 March 2013, while surveying for *H. l. subcaudalis* at Laughlin Air Force Base (LAFB) in southern Val Verde County, Texas, we observed two of the lizards retreat into Mexican Ground Squirrel burrows. We observed the behavior again on 16 April and 21 May 2013. Altogether, we observed the behavior eight times (out of 16 total observations). Of the eight lizards not observed to escape into ground squirrel burrows, two attempted to hide under the tires of our vehicle, one dashed across the road ahead of us and we couldn't determine what type of refuge it took, and five were captured by running them down on foot before they could find any type of escape shelter.

The Southern Spot-tailed Earless Lizard occurs on relatively flat substrates composed of soils that are loamy, loamy-clay, clay-loam, clay, rarely sandy loam, and never pure sand (Axtell 1956, *op. cit.*; Duran and Axtell 2010. Rept. to Texas Parks and Wildlife Dept., Contract #199464). The habitat at LAFB where this population occurs includes about 718 ha on and around aircraft runways in the western part of the base. The substrate is flat, loamy, and hard-packed. The site is sparsely vegetated, even when rainfall is near the 43.6 cm yearly average for Del Rio, Texas, but at the time of our visits, the region was experiencing drought, vegetation was even more sparse than usual, and lizards were quite conspicuous when present. The site is mown frequently to about 15 cm, mostly to discourage birds that might collide with aircraft. Several decades of mowing has replenished topsoil, has converted former agricultural fields and overgrazed thornscrub into grassland, and has, inadvertently, restored and maintained habitat for *H. l. subcaudalis*. Another result of the continuous mowing is that, except for an occasional stunted *Prosopis glandulosa* (Honey Mesquite) and a few stands of denser grass in moist depressions, the landscape mostly lacks escape cover, such as tall grass, dead or fallen trees, low growing shrubs, leaf litter, and cacti that might be available under different management regimes. Additionally, LAFB is enclosed by high fencing which excludes people and most medium-sized burrowing mammals. We observed numerous 1.9–2.5 cm diameter burrows, probably created by small rodents, but these burrows may have been too small for utilization by *H. l. subcaudalis*, and we saw no evidence that it was using them. We found no published or anecdotal reports of *H. lacerata* creating its own burrows. We did not observe *H. l. subcaudalis* escaping into refugia other than ground squirrel burrows. That we were able to catch lizards by running them down on foot may be the most informative anecdote to illustrate the paucity of escape cover at this site.

Lacking other types of refugia, *H. l. subcaudalis* appears to be dependent on ground squirrel burrows for escape cover at this location. The relationship between *I. mexicanus* and *H. l. subcaudalis* at this site is an apparent case of commensalism.

The Southern Spot-tailed Earless Lizard has been extirpated from much of its historic range. The observations at LAFB were the first reported observations of the subspecies since one individual was caught in a pitfall trap on the Chaparral Wildlife Management Area in LaSalle Co., Texas, in 1997 (Duran and Axtell 2010, *op. cit.*). The specimens we collected at LAFB were the first since a specimen was taken by Andy Price in Kinney Co., Texas in 1993 (Duran and Axtell 2010, *op. cit.*).

Limited knowledge of the life history requirements of *H. l. subcaudalis* has made planning effective conservation difficult. Evidence of the subspecies' close relationship to ground squirrels at this location may provide an important clue to restoring and maintaining populations, particularly in cases where man-made disturbance has created conditions under which the availability of escape cover may be a limiting factor.

This work was performed under Texas Parks and Wildlife Department Scientific Research Permit #SPR-0302-204. The live specimens were donated to the Fort Worth Zoo in Fort Worth, Texas. The zoo is attempting to breed the subspecies in captivity in hopes of reintroducing it into the wild.

We would like to thank the staff at Laughlin Air Force Base for permitting and participating in this research.

***JAPALURA SWINHONIS* (Swinhole's Japalura) and *TAKYDROMUS SAUTERI* (Sauter's Grass Lizard). PREDATION.** On 25 September 2013 at 0912 h along the roadside on Orchid Island, Taiwan (22.03333°N, 121.00916°E; 70 m elev.), one of us (CMW) observed and photographed an adult male *Japalura swinhonis* predating an adult *Takydromus sauteri*. The adult grass lizard was being consumed tail-end first (Fig. 1). During our observations, the *J. swinhonis* carried its prey from the ground up onto the trunk of a tree. Other *T. sauteri* individuals were observed on leaves of Japanese silver-grass (*Miscanthus floridulus*) along the forest edge in the vicinity. Most individuals move from leaf to leaf or are active on the ground and at night some individuals rest on the upper surface of a leaf (Huang 2006. J. Herpetol. 40:267–273). *Japalura swinhonis* is a sit-and-wait forager, which perches on tree trunks or on the ground at the edges of forests on Orchid Island. Previously, *J. swinhonis* was known to consume invertebrates exclusively, including ants (50%) and crickets (16.67%)

PHOTO BY C. M. WANG

FIG. 1. Adult male *Japalura swinhonis* consuming an adult *Takydromus sauteri* tail-end first.

(Huang 2007. Zool. Sci. 24:181–188). These two lizard species commonly co-occur along forest edges on Orchid Island, Taiwan (Huang 2004. Ph.D thesis, Cornell University, Ithaca, New York), which could result in substantial overlap between them.

***LEPIDOPHYMA GAIGEAE* (Gaige's Tropical Night Lizard). ENDOPARASITES.** *Lepidophyma gaigeae* occurs in Querétaro and Hidalgo, Mexico (Bezy and Camarillo 2002. Nat. Hist. Mus. Los Angeles Co., Contrib. Sci. 493:1–41). Goldberg et al. (2002. Texas J. Sci. 54:282–284) previously reported one species of Cestoda, *Bitegmen gerrhonoti*, and two species of Nematoda, *Spauligodon giganticus* and *Ascaridia* sp., in *L. gaigeae*. The purpose of this note is to add to the helminth list for *L. gaigeae*.

Two *L. gaigeae* (mean SVL = 58.0 mm ± 2.8 SD, range = 56–60 mm) collected August 1972 in Querétaro, Mexico and deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA as LACM 106808, 106809 were examined for helminths.

The digestive tract was removed through a mid-ventral incision and its contents were examined for helminths using a dissecting microscope. Only nematodes were found, which were cleared in a drop of lactophenol on a coverslipped microscope slide and studied under a compound microscope. One species of Nematoda, *Spauligodon oxkutzcabiensis*, was found in the intestines (N = 21, prevalence [number infected/number examined × 100] = 100%; mean intensity [mean number infected individuals] = 10.5 ± 12.0 SD, range = 2–19. Voucher helminths were deposited in the United States National Parasite Collection, Beltsville, Maryland, USA as USNPC 107882.

Spauligodon oxkyutzcabiensis was described from *Thecadactylus rapicauda* collected in the Yucatán by Chitwood (1938. Publ. Carneg. Inst. Washington 491:52–66) and is commonly found in lizards from Mexico and Central America. The distribution of hosts for *S. oxkutzcabiensis* is summarized in (Goldberg and Bursey 2012. Comp. Parasitol. 79:269–274). Infection occurs from contact with contaminated substrate or conceivably from licking the ground (see Goldberg and Bursey 1992. J. Parasitol. 78:539–541). *Spauligodon oxkutzcabiensis* is separated from the congener *S. giganticus* based on ornamentation of the eggs and number of spines on the tail of the female; eggs of *S. giganticus* with one polar knob, eggs of *S. oxkutzcabiensis* with a knob on each pole; tail of female *S. giganticus* with 10–11 spines, tail of female *S oxkutzcabiensis* with 13–15 spines (Chitwood, *op. cit.*; Read and Amrein 1953. J. Parasitol. 39:365–370). Both *S. giganticus* and *S. oxkutzcabiensis* have previously been reported in different representatives of sceloporine lizards from Mexico, including *Sceloporus grammicus* and *S. mucronatus* (Goldberg et al. 2003. Southwest. Nat. 48:208–217. *Lepidophyma gaigeae* represents a new host record for *Spauligodon oxkutzcabiensis*.

We thank G. Pauly (LACM) for permission to examine *L. gaigeae*.

STEPHEN R. GOLDBERG, Natural History Museum of Los Angeles County, Herpetology Section, Los Angeles, California 90007, USA (e-mail: sgoldberg@whittier.edu); **CHARLES R. BURSEY,** Pennsylvania State University, Shenango Campus, Biology Department, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu); **JEANNETTE ARREOLA,** Whittier College, Biology Department, Whittier, California 90608, USA (e-mail: jarreolea@poets.whittier.edu).

***LEPIDOPHYMA SYLVATICUM* (Madrean Tropical Night Lizard). ENDOPARASITES.** *Lepidophyma sylvaticum* occurs along the Sierra Madre Oriental from Nuevo León to Veracruz, Mexico (Bezy and Camarillo R. 2002. Nat. Hist. Mus. Los Angeles Co., Contrib. Sci. 493:1–41). To our knowledge, there are no reports of helminths from *L. sylvaticum*. The purpose of this note is to establish the initial helminth list for *L. sylvaticum*.

Eight *L. sylvaticum* (mean SVL = 79.0 mm ± 7.3 SD, range = 70–90 mm) collected in 1973 and deposited in the herpetology collection of the Natural History Museum of Los Angeles County, Los Angeles, California, USA (LACM 106744–106746, Hidalgo state, Mexico; LACM 106781–106785, Nuevo León state, Mexico), were examined for helminths.

The digestive tract was removed through a mid-ventral incision and its contents were examined for helminths using a dissecting microscope. Only nematodes were found, which were cleared in a drop of lactophenol on a coverslipped microscope slide and studied under a compound microscope. Four species of Nematoda were found: *Aplectana herediaensis (*small, large intestines, N = 1187), prevalence (number infected/number examined × 100) = 100%; mean intensity (mean number infected individuals) = 148.4 ± 99.7 SD, range = 1–292; *Parapharyngodon alvarengai* (large intestine, N = 2), prevalence = 13%); *Physaloptera* sp. (third stage larvae, stomach, N = 5), prevalence = 38%, mean intensity 1.7 ± 1.2 SD, range = 1–3; ascarid larvae (body cavity, N = 2), prevalence = 13%.

Voucher helminths were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland, USA as: *Aplectana herediaensis* (USNPC 107962, 107963); *Parapharyngodon alvarengai* (USNPC 107694); *Physaloptera* sp. (USNPC 107695); ascarid larvae (USNPC 107696).

Aplectana herediaensis was described from *Lepidophyma flavimaculatum* from Costa Rica (Bursey et al. 2006. Carib. J. Sci. 42:164–170) and was later found in *L. flavimaculatum* from Panama (Bursey et al. 2007. Comp. Parasitol. 74:108–140) and *L. micropholis* from San Luis Potosí (Goldberg and Bursey 2011 Herpetol. Rev. 43:648–649). *Parapharyngodon alvarengai* was described from *Mabuya maculata* (currently *Trachylepis atlantica*) from Brazil by Freitas (1957. Mem. Instit. Oswaldo Cruz 55:21–45) and is known from the lizards *Anolis nebulosus, Phyllodactylus lanei, Sceloporus nelsoni* and *Urosaurus auriculatus* of Mexico as well as *Mesoscincus managuae* from Nicaragua and *Ameiva ameiva, Hemidactylus agrius* and the toad *Rhinella icterica* from Brazil (Anjos et al. 2011. Neotrop. Helminthol. 5:285–290; Goldberg and Bursey. 2012. Comp. Parasitol. 79:269–274). There are many reports of amphibians and reptiles containing third stage larvae of *Physaloptera* sp. but no adults (Goldberg et al. 1993. Bull. South. California Acad. Sci. 92:43–51; Goldberg et al. 2009. Comp. Parasitol. 76:258–266). These amphibians and reptiles likely serve as paratenic (= transport) hosts with development completed in a carnivore that feeds on them. Vertebrates typically serve as intermediate hosts for larval ascaroids in which development to the stage infective to the definitive host occurs (Anderson 2000. Nematode Parasites of Vertebrates, Their Development and Transmission. CABI Publishing Oxon, UK. 650 pp.) *Lepidophyma sylvaticum* represents a new host record for *Aplectana herediaensis, Parapharyngodon alvarengai, Physaloptera* sp. (3rd stage larva), and ascarid larvae.

We thank G. Pauly (LACM) for permission to examine *L. sylvaticum*.

STEPHEN R. GOLDBERG, Natural History Museum of Los Angeles County, Herpetology Section, Los Angeles, California 90007, USA (e-mail:

sgoldberg@whittier.edu); **CHARLES R. BURSEY,** Pennsylvania State University, Shenango Campus, Biology Department, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu); **JEANNETE ARREOLA,** Whittier College, Biology Department, Whittier, California 90608, USA (e-mail: jarreola@ poets.whittier.edu).

***LEPIDOPHYMA TUXTLAE* (Tuxtla Tropical Night Lizard). ENDOPARASITES.** *Lepidophyma tuxtlae* occurs from the Sierra de Los Tuxtlas of central Veracruz west and southward to northern Oaxaca and northern Chiapas, Mexico (Calderón Mandujano et al. 2007. *In* IUCN 2013. IUCN Red List of Threatened Species. Version 2013.2 downloaded on 13 December 2013). To our knowledge, there are no reports of helminths from *L. tuxtlae*. The purpose of this note is to establish the initial helminth list for *L. tuxtlae*.

Three *L. tuxtlae* (mean SVL = 60.0 mm ± 2.0 SD, range = 58–62 mm) collected July 1984 from Veracruz, Mexico and deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM 136354, 136357, 136358) were examined for helminths.

The digestive tract was removed through a mid-ventral incision and examined for helminths using a dissecting microscope. Only nematodes were found, which were cleared in a drop of lactophenol on a coverslipped microscope slide and studied under a compound microscope. One species of Nematoda, *Aplectana herediaensis*, was found in the intestines (N = 209, prevalence [number infected/number examined × 100] = 100%; mean intensity [mean number infected individuals] = 69.7 ± 20.2 SD, range = 58–93). Voucher helminths were deposited in the United States National Parasite Collection Beltsville, Maryland as USNPC 107883.

Aplectana herediaensis was described from *Lepidophyma flavimaculatum* from Costa Rica (Bursey et al. 2006. Carib. J .Sci. 42:164–170) and was later found in *L. flavimaculatum* from Panama (Bursey et al. 2007. Comp. Parasitol. 108–140) and *L. micropholis* from San Luis Potosí, Mexico (Goldberg and Bursey 2012. Herpetol. Rev. 43:648–649). *Lepidophyma tuxtlae* represents a new host record for *Aplectana herediaensis*.

We thank G. Pauly (LACM) for permission to examine *L. tuxtlae*.

***OPLURUS QUADRIMACULATUS* (Dumeril's Madagascar Spiny-tailed Iguana). PREY AND PREDATORY BEHAVIOR.** Members of the Old World family Opluridae are known to be mainly insectivorous but occasionally include vertebrates and plant materials in their diet (Brillet 1982. Revue d'Ecologie - la Terre et la Vie 36:79–148; Delheusy and Bels 1992. J. Exp. Biol. 170:155–186; Mori and Randriamahazo 2002. Afr. J. Ecol. 40:61–64; Cadle 2003. *In* Goodman and Benstead [eds.], The Natural History of Madagascar, pp. 983–986. Univ. Chicago Press, Chicago, Illinois; Randriamahazo and Mori 2012. Curr. Herpetol. 31:8–13). Specific prey species for the rupicolous species *Oplurus quadrimaculatus* are relatively unknown. Herein, a case of predation on *Palpares amitinus* by *O. quadrimaculatus* is described.

On 14 December 2007, Isalo National Park in the Ihorombe region of Madagascar was visited, which is home to both *O. cuvieri* and *O. quadrimaculatus*. These lizards can be approached and observed from fairly close distances. At 1145 h, the foraging behavior of an adult male *O. quadrimaculatus* was observed. *Palpares amitinus* is an endemic but rather widespread and common species of ant lion in Southern Madagascar. The movement of an airborne adult ant lion caught the lizard's attention at which time it ran after the insect and jumped at it with its mouth open. Only at the third jump was the ant lion grabbed successfully, after which it was eaten whole. Jumps ranged approximately 20–45 cm vertically and 50–100 cm horizontally.

I thank V. J. T. Loehr and A. Mori for reviewing the first draft of this correspondence and A. Levente, Director of the Rippl-Rónai Museum, for identifying the species of ant lion.

***PHRYNOSOMA CORNUTUM* (Texas Horned Lizard). MALE-MALE INTERACTIONS.** Male-male interactions in *Phrynosoma* are generally fleeting and aggressive, frequently characterized by head-bobbing, pushups, and reciprocal vent sniffing, followed by the individuals moving away from one another (Whitford and Whitford 1973. Herpetologica 29:191–192; Whitford and Bryant 1979. Ecology 60:686–694; Tollestrup 1981. Herpetologica 37:130–141). Few studies have reported overlap of home ranges (Munger 1984. Oecologia 62: 351–360). Here we report on two adult males who maintained close association over a period of three days.

At 0915 h on 11 July 2013, while conducting a daily resight on a radio-tagged male (SVL = 63 mm) in central Texas, USA (30.579634°N, 99.466518°W; datum WGS84), we encountered and marked a previously untagged adult male (SVL = 60 mm) located approximately 0.5 m away. At 1220 h on 12 July 2013, we returned to the area to resight the individuals. Both were buried in parallel beneath the same Narrow-leaf Yucca plant (*Yucca reverchonii*, Fig. 1). At 1445 h on 13 July 2014, both were again buried beneath the same yucca plant, but their directions had changed and the individuals were now buried facing opposite directions. By 1803 h on 14 July 2013, both individuals were buried greater than 5 m from each other. These observations indicate that male

FIG. 1. Two tagged male *Phrynosoma cornutum* buried in parallel.

P. cornutum may be more tolerant of other males, at least under some circumstances, than previously suggested.

We thank Texas Army National Guard, Texas Parks and Wildlife Department, and the Fort Worth Zoo for funding, and Gad Perry for valuable input.

***PTYCHOGLOSSUS FESTAE* (Peracca's Largescale Lizard). NESTING.** *Ptychoglossus festae* is an uncommon gymnophthalmid lizard distributed from eastern Panama to northwestern Colombia. It occurs in forest leaf litter in areas of lowland tropical rainforest throughout the departments of Chocó, Córdoba, and Antioquia in Colombia, at 30–820 m elevation. Little else is known of the natural history of this species (Harris 1994. Herpetol. Monogr. 8:226–275). Here we report communal egg-laying in *P. festae* within a rotten log in tropical rainforest in the Nature Reserve Civil Society Ormuz, Vereda Las Parcelas Capitán, Corregimiento of Titumate, municipality of Unguia, department of Chocó, Colombia (8.266199°N, 77.089885°W; datum WGS 84) in an area studied from 14–25 September 2013.

At the study site, we found two nests very close to one another, each clutch containing two viable eggs. All eggs were at nearly the same state of development, as all hatched between one to three days following their collection. In addition, a gravid female *P. festae* was found about to lay two eggs next to the other nests. The four eggs weighed on average 0.5 g (range = 0.4–0.6 g), average width 7.33 mm (range = 6.70–8.00 mm), average length 11.14 mm (range = 10.70–11.60 mm). We measured the four neonates, as follows: average LRC 22.86 mm (range = 22.04–23.20 mm), average LC 28.8 mm (range = 26.4–29.10 mm), and average weight 0.30 g (range = 0.28–0.33 g).

This is the first report for conspecific communal oviposition of *P. festae* (Fig. 1). In lizards, communal nests have been observed in various families, including the Gymnophthalmidae (Magnusson and Lima 1984. J. Herpetol. 18:73–75; Radder and Shine 2007. J. Anim. Ecol. 76:881– 887; Doody 2009. Q. Rev. Biol. 84[3]:229–252; Medina-Rangel 2013. Herpetol. Rev. 44:312–313). Although communal oviposition in reptiles has been attributed to scarcity of nest sites offering suitable incubation conditions (direct fitness benefits accruing from the proximity of other eggs; Radder and Shine, *op. cit.*; Doody, *op. cit.*), the tropical rainforest habitat discussed herein provides abundant nesting sites. As affirmed by Doody (*op. cit.*), communal nesting behavior may provide an evolutionary advantage to reptiles, given the lack of parental care in most species, despite the abundance of adequate nest sites. The reproductive aspect of Colombian Gymnophthalmidae is poorly known and information on nests, oviposition, incubation period, and hatchlings is lacking. This report provides the first data on communal nesting for *Ptychoglossus* species in Colombia.

FIG. 1. Eggs at different stages of development and one newly hatched young of *Ptychoglossus festae* observed at a communal oviposition site within a rotten log in Colombia.

***PYGOPUS NIGRICEPS* (Western Hooded Scaly-foot). TAIL AUTOTOMY.** Some lizards autotomize their tails in response to predatory attacks. Although considerable study has been devoted to understanding the evolution of voluntary tail loss, especially in skinks and geckos (Arnold 1984. J. Nat. Hist. 18:127–169), variation in the "behavior" of the tail among species has not been quantified within a comparative context, at least partly because we lack autotomy observations in nature for a large number of species. Autotomy observations on additional species would thus facilitate our understanding of the phenomenon. Herein we report on an observation of unusual and possibly unique tail autotomy behavior in *Pygopus nigriceps* from tropical Australia.

At ~1900 h on 15 December 2008, while driving along the main highway near Uluru (Ayers Rock), Northern Territory, Australia (25.370503°S, 131.086223°E), we stopped for a lizard that was squirming about on the road. Upon inspection we determined that the lizard was *P. nigriceps*, and had just been run over by a vehicle (one had just sped past us). The lizard appeared to be dead (wounds to the body) but the action of the tail, which had broken from the body but was still connected to it by a small piece of skin, was pulling the body around. At this time, curious about how the tail would move without the lizard, we freed the tail from the body by removing the connecting skin. To our surprise, the tail began to move in a deliberate sinuous fashion like a snake (or legless lizard) away from the body; the anterior end of the tail was raised somewhat, giving the appearance of a head. Remarkably, the tail moved > 3 m from the body, off the road. The path of the tail did not track in a straight line, but also in a somewhat sinuous fashion. After about four minutes, the tail stopped moving horizontally, but continued to wiggle in place, in a back and forth fashion. After about another minute the tail ceased to move, coming to rest on the road shoulder. The body did not move again. The weather was overcast and warm (~25°C); however, a shower had passed through the area that evening, and storms had been present the previous few days.

The tail autotomy we observed in *P. nigriceps* was unusual and possibly unique. Most observations of tail autonomy in lizards involve somewhat random movement patterns within a small area (e.g., within 0.5 m^2, pers. obs.). The tail of the *P. nigriceps*, in sharp contrast, moved well away from the body in a very deliberate fashion, coming to rest meters away. The movement of the tail was reminiscent of a legless lizard or snake, and the pathway would serve to lead the predator well away from the lizard. In our case, we could not observe behavior in the (dead)

lizard as the tail moved away, but future observations should note if the lizard moves in the opposite direction to that of the tail. Further observations are needed to confirm this unusual autotomy in *P. nigriceps*, in congeners, and in other similarly-built pygopodids.

J. SEAN DOODY, Department of Ecology and Evolutionary Biology, University of Tennessee, 569 Dabney Hall, Knoxville, Tennessee 37996-1610, USA (e-mail: jseandoody@gmail.com); **CHRISTINA M. CASTELLANO**, Utah's Hogle Zoo, 2600 East Sunnyside Ave., Salt Lake City, Utah 84108, USA (e-mail: woodturtle@gmail.com).

***SALTUARIUS SWAINI* (Southern Leaf-tailed Gecko). TAIL AUTOTOMY.** Some lizards autotomize their tails in defense of predators, and considerable study has been devoted to understanding the evolution of voluntary tail loss, especially in skinks and geckos (Arnold 1984. J. Nat. Hist. 18:127–169). Variation in the "behavior" of the tail among species has not been quantified within a comparative context, at least partly because we lack autotomy observations for a large number of species (Higham and Russell 2010. Biol. Lett. 6:70–73). Observations for more species are needed to facilitate our understanding of how autotomy is used and how it evolves. Herein we report on an observation of unusual and possibly unique tail autotomy behavior in *Saltuarius swaini*. The tail of *S. swaini* is flat and shaped somewhat like an upside-down tear, with a distinct attenuated tip (Fig. 1).

On 7 May 2001 one of us (SD) inadvertently dislodged the tail from an adult male *S. swaini* while removing the lizard from the road at O'Reilly's Resort in Lamington National Park, Queensland, Australia (28.229462°S, 153.133309°E). The (entire) autotomized tail dropped onto the road and immediately exhibited unusual locomotion for an autotomized tail. The tail, which was an original tail based on the presence of spines (as in Fig. 1), flipped sideways in one direction repeatedly, resulting in an overall rolling action that tracked in a large circle with a diameter of approximately 0.5 m. After about two minutes, movement of the tail slowed considerably, during which time SD noticed that the tail tip was the lever that flipped the tail. At this time SD quickly removed the tip of the tail with a knife, and this caused the tail to cease flipping and thus rolling. The tip-less tail rocked back and forth in place for another minute or so before it ceased movement altogether. The time was 2030 h on a misty night with an air temperature of 18°C.

PHOTOS BY S. MACDONALD

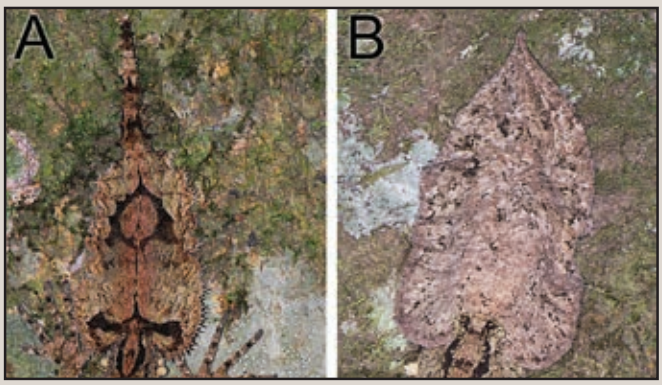

FIG. 1. *Saltuarius swaini*, showing the shape of the (A) original tail and (B) regenerated tail. During autotomy in the original tail, the tip of the tail acts as a lever to continuously flip the autotomized tail in one direction, resulting in the tail 'rolling' in a circular path well away from the body.

The tail autotomy SD observed in *S. swaini* is apparently unique. The flat shape of the tail, along with the tip as a lever, resulted in the tail moving non-randomly over a considerable area, compared to the more usual movements of autotomized lizard tails that generally move rapidly and somewhat randomly within a smaller area (pers. obs.). Although tail autotomy is presumed to have evolved to distract the would-be predator from the lizard, non-random tracking of the tail of *S. swaini* would seemingly provide a more deliberate path away from the lizard. Tests of the lizard's movements immediately following autotomy would be invaluable here. Moreover, the use of the tail-tip as a lever, coupled with little tail movement when the tip was removed, indicates that the tail tip may have evolved explicitly to serve an antipredator function. Comparative study of closely related members of the group with variation in tail shape and tip length could confirm the importance of the tail tip for autotomy in *S. swaini*, as well as determine how autotomy has been modified in this group of arboreal geckos. Also, the regenerated tails in this species exhibits a shorter tail tip, which may influence the behavior of the autotomized tail.

SEAN DOODY, Department of Ecology and Evolutionary Biology, University of Tennessee, 569 Dabney Hall, Knoxville, Tennessee 37996-1610, USA (e-mail: jseandoody@gmail.com); **STEWART MACDONALD**, Centre for Tropical Biology and Climate Change, James Cook University, Townsville, Queensland 4814, Australia (e-mail: stewart@ugmedia.com.au).

***SCELOPORUS NELSONI* (Nelson's Spiny Lizard). CESTODE ENDOPARASITES.** *Sceloporus nelsoni* ranges from southwest Chihuahua and southern Sonora, Mexico along Pacific slopes to Jalisco, Mexico (Lemos Espinal and Smith 2007. Amphibians and Reptiles of the State of Chihuahua, Mexico. Comisión Nacional Para Conocimiento y Uso de la Biodiversidad, Universidad Nacional Autónoma de Mexico, Tlalnepantl, edo. de México. 613 pp.). Currently, there are two helminth species known from *S. nelsoni*: *Parapharyngodon alvarengai* and *Strongyluris similis* (Mayén-Peña et al. 1998. J. Helminthol. Soc. Washington 65:108–111). The purpose of this note is to add to the helminth list of *S. nelsoni*.

A sample of 11 *S. nelsoni* (mean SVL = 54.6 mm ± 3.7 SD, range = 44–58 mm) collected in the vicinity of Alamos (27.00275°N, 108.9400°W), Sonora, Mexico in 1960 to 1963, 1966, 1975 and deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA was examined for helminths (LACM) 96211, 96216, 96218, 96225, 96226, 96229, 96232, 96234, 96235, 96240, 96241.

The body cavity was opened and the digestive tract removed, opened by a longitudinal incision and examined under a dissecting microscope. Only cestodes (from the small intestines of LACM 96218, 96240, 96241) were found, which were regressively stained in hematoxylin, mounted in Canada balsam, studied using a compound microscope and identified as *Oochoristica scelopori* (prevalence: number infected/number examined × 100 = 27%, mean intensity: mean number infected individuals ± 2.7 SD, range = 1–6). The finding of only one helminth species in *S. nelsoni* may reflect our small sample size. Voucher cestodes were deposited in the helminthological collection of the United States Parasite Collection (USNPC), Beltsville, Maryland, USA as *Oochoristica scelopori* USNPC (107888).

Oochoristica scelopori is common in sceloporine lizards from both Arizona (Goldberg et al. 1994. J. Helminthol. Soc. Washington 61:73–83) and Mexico (Goldberg et al. 2003. Southwest. Nat. 48:208–217) as well as other lizards from southern California

(Telford 1970. Amer. Midl. Nat. 83:516–554). Our diagnosis of *O. scelopori* is based on characters of Nearctic species of *Oochoristica* as listed in Table 2 of Bursey et al. (2010. Zootaxa 2715:45–54): neck present; circular suckers; 22–43 testes present in one cluster; ovary with large number of lobules. *Sceloporus nelsoni* represents a new host record for *Oochoristica scelopori*.

We thank G. Pauly (LACM) for permission to examine *S. nelsoni*.

STEPHEN R. GOLDBERG, Whittier College, Department of Biology, PO Box 634, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **CHARLES R. BURSEY,** Pennsylvania State University, Shenango Campus, Biology Department, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu); **JEANETTE ARREOLA,** Whittier College, Department of Biology, PO Box 634, Whittier, California 90608, USA (e-mail: jarreola@poets.whittier.edu).

***SCELOPORUS OCCIDENTALIS* (Western Fence Lizard) and *SCELOPORUS ORCUTTI* (Granite Spiny Lizard). FEEDING BEHAVIOR AND DIET.** On 17 April 2010 between 1115–1145 h, we observed five *Sceloporus occidentalis* and three *S. orcutti* preying on carpenter ants (*Camponotus*) approx. 6 km NW of Warner Springs, San Diego Co., California, USA (33.30502°N, 116.69444°W, datum WGS84; elev. 890 m). The *Camponotus* were emerging from their nest and swarming the surface of a granite boulder approximately 3 m diameter. The swarm (> 1000) covered approximately 75% of the boulder and consisted of an estimated 85% workers (sterile wingless females) and 15% winged queens and males. The ants are currently being described as a new species of *Camponotus* (P. Ward, pers. comm.).

Both *Sceloporus* species were employing ambush foraging behavior. The lizards were positioned on elevated ambush sites on the edge of an adjacent boulder in clear view of the ants. Occasionally a lizard would jump about 10 cm across a crevice to the adjacent boulder, run among the carpenter ants, capture a single ant, and then quickly retreat to its elevated perch to consume its prey. *Camponotus* are large, fiercely territorial ants. They do not sting, but the workers and soldiers can administer a powerful bite that is often accompanied by the release of formic acid (Hölldobler and Wilson 1990. The Ants. The Belknap Press of Harvard University Press, Cambridge, Massachusetts. 732 pp.). One male *S. occidentalis* (SVL = 75 mm) was collected (SDNHM 68935). Its stomach contents contained several *Camponotus* sp. (*sensu* Ward, *op. cit.*) consisting of one alate queen, two workers and ant fragments; one *Dermacentor occidentalis* (Arachnidae: Ixodidae); an unidentified Coleoptera, and an unidentified Hemiptera.

Jumping to catch insect prey by *Sceloporus occidentalis* (Stone 1942. Copeia 1942:129) and ants as prey for both *S. occidentalis* and *S. orcutti* has been previously reported (Mayhew 1963. Amer. Midl. Nat. 69:310–327; Johnson 1965. Herpetologica 21:114–117; Clark 1973. Herpetologica 29:73–75; Otvos 1977. Herpetol. Rev. 8:6–7). This is the first report of these species consuming *Camponotus*. The feeding behavior described demonstrates an ability to successfully and repeatedly capture and consume potentially harmful prey while minimizing injury. Our observation of the aggregation of feeding in syntopic *S. occidentalis* and *S. orcutti* from the same outcrop suggests that the lizards temporarily suspend interspecific territoriality (Creusere and Whitford 1982. *In* Scott [ed.], Herpetological Communities, pp. 121–127. U.S. Dept. Interior, Fish and Wildlife Service, Research Report 13) to take advantage of an abundant food supply.

Our thanks to Phillip S. Ward, Norman J. Scott, Jr. and Bradford D. Hollingsworth.

EDWARD L. ERVIN, Merkel & Associates, Inc., 5434 Ruffin Road, San Diego, California 92123, USA (e-mail: eervin@merkelinc.com); **CLARK R. MAHRDT**, Herpetology Department, San Diego Natural History Museum, P.O. Box 121390, San Diego, California 92112, USA.

***SCELOPORUS OMILTEMANUS* (Southern Cleft Lizard). ENDOPARASITES.** *Sceloporus omiltemanus* is restricted to Guerrero and Oaxaca, Mexico (Martínez-Méndez and Méndez-De La Cruz 2007. Zootaxa 1609:53–68; Uetz and Hosek [eds.] 2014. The Reptile Database, http://www.reptile-database.org, accessed 03 February 2014). We know of no published reports of helminths for *S. omiltemanus*. The purpose of this note is to establish the initial helminth list for *S. omiltemanus*.

Four *S. omiltemanus* (mean SVL = 87.0 mm ± 12.7 SD, range = 72–98 mm) were examined from the herpetology collection of the Los Angeles County Museum of Natural History (LACM) collected 1973 (LACM 109214) and 1977 (LACM 127038–127040). Specimens were from the vicinity of Carrizal de Bravo (17.621111°N, 99.838056°W, elev. 2400 m), Guerrero, Mexico.

The body cavity was opened and the digestive tract was removed, opened by a longitudinal incision and examined under a dissecting microscope. Cestodes were regressively stained in hematoxylin, mounted in Canada balsam, and studied using a compound microscope. Nematodes were cleared in a drop of lactophenol on a glass slide, cover slipped and studied under a compound microscope. Found were one species of Cestoda: *Oochoristica scelopori* (infection site, small intestine), helminths (N) = 8, prevalence = number infected/number examined × 100 = 50%, mean intensity ± SD, mean number infected individuals with range = 4.0 ± 8.5 SD, range = 1–7, and four species of Nematoda: *Spauligodon giganticus* (large intestine, (N) = 13, prevalence = 100%, mean intensity = 8.5 ± 3.1 SD, 6–13; *Strongyluris similis* (large intestine, (N) = 39, prevalence = 75%, mean intensity ± SD = 13.0 ± 11.8, 3–26; *Oswaldocruzia* sp. (stomach, small intestine), (N) = 5, prevalence = 25%, and *Physocephalus* sp. (stomach wall), (N) = 5, prevalence = 25%. Voucher helminths were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as: *Oochoristica scelopori* (USNPC 107891), *Spauligodon giganticus* (USNPC 107893), *Strongyluris similus* (USNPC 107894), *Oswaldocruzia* sp. (USNPC 107895), *Physocephalus* sp. (USNPC 107897).

Oochoristica scelopori is common in sceloporine lizards from both Arizona (Goldberg et al. 1994. J. Helminthol. Soc. Washington 61:73–83) and Mexico (Goldberg et al. 2003. Southwest. Nat. 48:208–217) as well as other lizards from southern California (Telford 1970. Amer. Midl. Nat. 83:516–554). Our diagnosis of *O. scelopori* is based on characters of Nearctic species of *Oochoristica* listed in Table 2 of Bursey et al. (2010. Zootaxa 2715:45–54): neck present, circular suckers, 22–43 testes present in one cluster, ovary with large number of lobules. *Spauligodon giganticus* is distinguished from *S. oxkutzcabiensis* which also occurs in Mexican sceloporines (Goldberg et al. 2003. Southwest. Nat. 48:208–217) on the basis of egg morphology: eggs of *S. giganticus* are lanceolate with a knob at the wide end; eggs of *S. oxkutzcabiensis* are lanceolate with a knob at each end (Bursey et al., 2005. J. Parasitol. 91:324–328. *Strongyluris similis* has been previously reported from sceloporines from both Mexico and the United States (Goldberg et al. 2003, *op. cit.*). Species of *Oswaldocruzia* sp. are found worldwide in the intestines of amphibians and reptiles (Anderson 2000. Nematode Parasites of Vertebrates Their Development and Transmission. CABI Publishing, Oxon, UK. 650 pp.). Larvae of *Physocephalus* were previously reported from

cysts in the stomach walls of Mexican sceloporines (Goldberg et al. 2003, *op. cit.*). As no further development occurs, lizards probably serve as paratenic (transport) hosts for larvae of *Physocephalus* sp. *Sceloporus omiltemanus* represents a new host record for *O. scelopori, S. giganticus, S. similis, Oswaldocruzia* sp., *Physocephalus* sp.

We thank G. Pauly (LACM) for permission to examine *S. omiltemanus*.

STEPHEN R. GOLDBERG, Natural History Museum of Los Angeles County, Herpetology Section, Los Angeles, California 90007, USA (e-mail: sgoldberg@whittier.edu); **CHARLES R. BURSEY,** Pennsylvania State University, Shenango Campus, Biology Department, Sharon, Pennsylvania 16146, USA (e-mail: cxb13@psu.edu); **JEANETTE ARREOLA,** Whittier College, Department of Biology, PO Box 634, Whittier, California 90608, USA (e-mail: jarreola@poerts.whittier.edu).

***SCELOPORUS PARVUS* (Blue-bellied Lizard). FEMALE AGGRESSION.** Aggressive displays are used by lizards in the genus *Sceloporus* for social communication (e.g., Carpenter 1978. Contrib. Biol. Geol. Milwaukee Publ. Mus. 18:1–71). Previous studies of aggressive signaling have focused mostly on males, but some female *Sceloporus* use aggressive displays in social interactions (Woodley and Moore 1999. Horm. Behav. 35:205–214; Hews et al. 2004. Anim. Behav. 68:1201–1207). Here, I provide what I believe to be the first reported observations of aggressive signaling by female *Sceloporus parvus*. Both observations were made in the breeding season on a population of *S. parvus* located ca. 10 km W of San Joaquín, Querétaro, Mexico (20.89668°N, 99.65568°W, datum WGS84; 2177 m elev.).

On 31 May 2013 I observed a male *S. parvus* basking on a boulder. The lizard abruptly moved to the ground on the opposite side of the boulder and was out of view for ca. 10 sec. When I relocated the focal male, I observed him consuming an unidentified grasshopper with the head protruding from the lizard's mouth. A female *S. parvus* quickly approached the male from ca. 1 m away in a series of three short-distance movements. Each movement was made directly toward the male and interrupted by a bout of 2–3 push-up displays by the female. The push-up displays involved movement of the front two legs with slight dorsolateral compression, a posture typically seen in aggressive interactions of *Sceloporus*. When the female was ca. 15 cm from the male, he retreated beneath the boulder with the partially consumed grasshopper and was followed rapidly by the female.

On 1 June 2013 I observed a *S. parvus* female basking on a rock when a male approached from ca. 4 m away while performing shudder courtship displays. When the male was ca. 2 m away from the female, she turned laterally to present her left side to the male, arched her back, and compressed her body dorsolaterally. Similar postures have been described as courtship rejection displays in other lizards (Cooper and Greenberg 1992. *In* Gans and Crews [eds.], Hormones, Brain, and Behavior, Biology of the Reptilia Vol. 18, Physiology E, pp. 298–422. University of Chicago Press, Chicago, Illinois). When the female assumed the posture, the male terminated a shudder display and moved away from the female. The female remained in the aggressive posture until the male entered a shrub ca. 1.5 m away.

JAKE ALLEN PRUETT, Department of Biology, Indiana State University, 700 North Seventh Street, Terre Haute, Indiana 47809, USA; e-mail: jpruett1@sycamores.indstate.edu.

***SCELOPORUS PARVUS* (Blue-bellied Lizard). REPRODUCTION.** *Sceloporus parvus* is known from the Sierra Madre Oriental of northeastern México; recorded from the highlands of Coahuila, Nuevo León, Tamaulipas, San Luis Potosí, and Hidalgo (Lemos Espinal and Smith 2007. Amphibians and Reptiles of the State of Coahuila. CONABIO/UNAM. 550 pp.). The natural history of this species is poorly understood and no data on reproduction are available. Lemos Espinal and Smith (2007, *op. cit.*) comment that this species is probably oviparous.

On 6 April 2012, one gravid female *S. parvus* (MZFC 29625; Colección Herpetológica del Museo de Zoología Alfonso L. Herrera Facultad de Ciencias UNAM) was collected in oak forest habitat at the Rancho el Chupadero, Municipality Ocampo, Coahuila, México (27.1655°N, 102.5722°W, datum WGS84; 2012 m elev.). The female measured 44.7 mm SVL, body mass was 12.3 g. The female contained a clutch size of 3 eggs: egg mass 0.24–0.28 g (mean = 0.26); egg length 9.38–9.65 mm (mean = 9.52). This information confirms the oviparity of the species and represents the first clutch size reported for *S. parvus*.

We thank the American Museum of Natural History (Theodore Roosevelt Memorial Fund Grant Award to MTO and UOGV), WWF-Alianza Carlos Slim (L039), and CONABIO (JF065) for financial support.

L. Minckley, Pte. Carranza 104, Nte., Cuatro Ciénegas de Carranza, Coahuila, México 27640.

***SCELOPORUS SINIFERUS* (Longtail Spiny Lizard). ENDOPARASITES.** *Sceloporus siniferus* occurs along the Pacific slope of southern Mexico from Guerrero to Guatemala and inland through the states of Morelos, Oaxaca, and Chiapas (Uetz and Hosek [eds.], The Reptile Database, http://www.reptile-database.org, accessed 07 Nov 2013). We know of no helminth records from this species. The purpose of this note is to establish the initial helminth list for *S. siniferus*.

A sample of nine *Sceloporus siniferus* (mean SVL = 51.6 mm ± 4.3 SD, range = 45–49 mm collected in Oaxaca, Mexico during 1957, 1964, and 1965 and deposited in the herpetology collection of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA as LACM 61964–61968, 64494–64496, 97412 was examined.

The body cavity was opened and the digestive tract removed, opened by a longitudinal incision and examined under a dissecting microscope. One nematode was found in the stomach of LACM 61965 and two were found in LACM 64494 (one in the stomach, one in the small intestine). Nematodes were cleared in a drop of lactophenol on a glass slide, coverslipped, studied under a compound microscope and identified as *Physaloptera retusa, (*prevalence: number infected/number examined × 100 = 22%) mean intensity: mean number infected individuals ± 1 SD = 1.5 ± 0.70 SD, range = 1, 2).Voucher helminths were deposited in the United States National Parasite Collection (USNPC), Beltsville, Maryland as *Physaloptera retusa* (USNPC 107887). *Physaloptera retusa* has the largest latitudinal geographic range of any Western Hemisphere nematode, occurring in lizards from North, Central and South America (Baker 1987. Synopsis of the Nematoda Parasitic in Amphibians and Reptiles. Mem. Univ. Newfoundland 11:1–325; Bursey et al. 2007. Comp.

Parasitol. 74:108–140). *Sceloporus siniferus* represents a new host record for *Physaloptera retusa*.

We thank G. Pauly (LACM) for permission to examine *S. siniferus*.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **CHARLES R. BURSEY,** Pennsylvania State University, Shenango Campus, Biology Department, Sharon, Pennsylvania 16146, USA (e-mail: exb13@psu.edu); **JEANETTE ARREOLA,** Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: jarreola@poets.whittier.edu).

***SCINCELLA LATERALIS* (Little Brown Skink). PREDATION.** *Scincella lateralis* is a small skink native to the southeastern USA, where it is depredated by a variety of snakes, spiders, and predatory birds. Other than shrikes (*Lanius*) and corvids, only a few passerine birds have been documented to depredate *S. lateralis*, including Eastern Meadowlarks (*Sturnella magna*; Kemmerer and Cline 1985. Herpetol. Rev. 16:27–28), and Eastern Bluebirds (*Sialia sialis*; Beane and Trail 1991. Herpetol. Rev. 22:99). On 30 December 2013 at 1330 h, I observed an Eastern Phoebe (*Sayornis phoebe*) eating an adult *S. lateralis* at the Falls Lake Dam in Wake Co., North Carolina, USA (35.939897°N, 78.582787°W, WGS84; eBird checklist http://ebird.org/ebird/view/checklist?subID=S16129770). The bird was shaking the lizard violently in its bill and beating it against the branch it was perched on, consistent with prey-killing behavior used by both shrikes and bluebirds. The skink had lost most of its tail, although it could not be determined whether this happened during this predation event or a previous one. Although two separate accounts document Eastern Phoebes eating small fish (Jung 1926. Bird-Lore 28:63–64; Binford 1957. Auk 74:264–265), this is apparently the first account of one eating a tetrapod vertebrate.

ANDREW M. DURSO, Department of Biology, Utah State University, Logan, Utah 84322, USA; e-mail: amdurso@gmail.com.

***SPHENOMORPHUS SCOTOPHILUS* (Spotted Forest Skink). REPRODUCTION.** *Sphenomorphus scotophilus* is scansorial and diurnal and is known from southern Thailand south through Peninsular Malaysia to possibly Sumatra (Grismer 2011a. Field Guide to the Amphibians and Reptiles of the Seribuat Archipelago [Peninsular Malaysia]. Edition Chimaira, Frankfurt am Main. 239 pp.). In the Seribuat Archipelago, gravid females carrying two eggs have been found during March, April, July, and September; hatchlings were observed in November (Grismer 2011b. Lizards of Peninsular Malaysia, Singapore and their Adjacent Archipelagos. Edition Chimaira, Frankfurt am Main. 728 pp.). In this note, we add information on the reproductive biology of *S. scotophilus* from a histological examination of gonadal material.

A sample of 48 *S. scotophilus* from West Malaysia collected 2001 to 2007 by LLG and deposited in the herpetology collection of La Sierra University, Riverside, California, USA was examined. The sample consisted of 29 adult males (mean SVL = 47.4 mm ± 4.7 SD, range = 35–58 mm), 18 adult females (mean SVL = 48.4 mm ± 3.0 SD, range = 44–54 mm), and one juvenile (SVL = 28 mm). *Sphenomorphus scotophilus* were collected in West (Peninsular) Malaysia (by state): Johor (N = 13), Pahang (N = 27), Penang (N = 3), Selangor (N = 5).

A cut was made in the lower abdominal cavity and the left testis or ovary was removed, embedded in paraffin, cut into 5 µm sections and stained with Harris hematoxylin followed by eosin counterstain. Enlarged follicles (> 4 mm) or oviductal eggs were counted. Histology slides were deposited in LSUHC.

Table 1. Monthly stages in the ovarian cycle of 18 adult female *Sphenomorphus scotophilus* from West Malaysia. *One oviductal female exhibited concurrent yolk deposition.

Month	N	Quiescent	Yolk deposition	Enlarged follicles > 4 mm	Oviductal eggs
March	5	2	0	1	2
July	13	2	2	0	9*

The only stage present in the testicular cycle was spermiogenesis in which the lumina of the seminiferous tubules were lined by sperm or clusters of metamorphosing spermatids. The following monthly samples of males were examined: March (N = 8), June (N = 2), July (N = 12), August (N = 5), September (N = 1), October (N = 1). The smallest reproductively active male (spermiogenesis) measured 35 mm SVL (LSUHC 8199) and was collected in September.

Four stages were present in the ovarian cycle (Table 1): 1) quiescent, no yolk deposition; 2) yolk deposition (basophilic vitellogenic granules in the ooplasm); 3) enlarged follicles > 4 mm; 4) oviductal eggs. One female with oviductal eggs (LSUHC 7278) was undergoing concurrent yolk deposition for a subsequent clutch indicating *S. scotophilus* can produce multiple egg clutches in the same year. Mean clutch size (N = 12) was 1.8 ± 0.39 SD, range = 1–2. The smallest reproductively active female (oviductal eggs) measured 44 mm SVL and was collected in July (LSUHC 4574). One juvenile (LSUHC 4702) of possible neonate size (SVL = 28 mm) was collected in July.

In view of the extended period in which reproductively active males were found and the observations of Grismer (2011b, *op. cit.*), *S. scotophilous* exhibits an extended reproductive cycle, in which breeding may be continuous.

STEPHEN R. GOLDBERG, Whittier College, Department of Biology, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **L. LEE GRISMER,** La Sierra University, Department of Biology, Riverside, California 92515, USA (e-mail: lgrismer@lasierra.edu).

***XANTUSIA ARIZONAE* (Arizona Night Lizard). REPRODUCTION.** *Xantusia arizonae* is endemic to Arizona west of the Verde River in the Weaver, Date Creek, and McCloud Mountains (Sinclair et al. 2004. Amer. Nat. 163:396–414). The species has been reported to give birth to one or two young in late August (Klauber 1931. Trans. San Diego Soc. Nat. Hist. 7:1–16; Brattstrom 1951. Herpetologica 7:143–144). The purpose of this note is to provide additional information on reproduction of *X. arizonae*.

Eleven *X. arizonae* consisting of one adult male (SVL = 46 mm), one subadult male (SVL = 43 mm), eight adult females (mean SVL = 55.0 mm ± 1.9 SD, range = 53–58 mm), and one unsexed subadult (SVL = 40 mm) in the herpetology collection of the Natural History Museum of Los Angeles County (LACM) were examined for reproductive activity. Eleven were collected in May 1982; one was collected in June 1982, all from the vicinity of Yarnell (34.2225°N, 112.7496°W), Yavapai Co.: LACM 134510–134516, 134524, 134526, 134530, 169268.

Ovaries and testes were histologically examined. Tissues were embedded in paraffin, histological sections were cut at 5

µm and stained with hematoxylin followed by eosin counterstain. Histology slides were deposited in LACM.

One *X. arizonae* male (SVL = 48 mm SVL) was undergoing spermiogenesis; lumina of the seminiferous tubules were lined by sperm or clusters of metamorphosing spermatids. One smaller male (SVL = 43 mm) exhibited early recrudescence in which seminiferous tubules contained 3–4 layers of primary spermatocytes with spermatogonia in the basal layer. It was considered to be a subadult.

Seven of eight females were undergoing yolk deposition with 1–2 follicles containing basophilic granules in the ooplasm. The other *X. arizonae* female (from June) contained two oviductal eggs; no embryos were visible. Mean clutch size for eight females was 1.8 ± 0.46 SD, range = 1–2. The smallest reproductively active females (vitellogenic granules in follicles) measured 53 mm SVL (LACM 134516, 162968).

In conclusion of this investigation, *X. arizonae* belongs to the group of xantusiids which breed in spring with young produced in late summer to early fall, including the congeners *X. riversiana* (Goldberg and Bezy. 1974. Herpetologica 30:350–360), *X. henshawi* (Lee 1975. Trans. San Diego Soc. Nat. Hist. 17:259–278), and *X. vigilis* (Miller 1948. Univ. California Publ. Zool. 47:197–213).

We thank G. Pauly (LACM) for permission to examine *X. arizonae*.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **ROBERT L. BEZY,** Section of Herpetology, Natural History Museum of Los Angeles County, Los Angeles, California 90007, USA (e-mail: robertbezy@gmail.com).

XANTUSIA BEZYI **(Bezy's Night Lizard). REPRODUCTION.** *Xantusia bezyi* is an Arizona endemic found east of the Verde River from the Mazatzal and Superstition Mountains east to the northwest base of the Pinal Mountains and south across the Gila River to the Galiuro Mountains (Sinclair et al. 2004. Amer. Nat. 163:396–414). The purpose of this note is to provide information on reproduction of *X. bezyi*.

Twenty-one *X. bezyi* consisting of seven adult males (mean SVL = 50 mm ± 2.4 SD, range = 48–53 mm), 11 adult females (mean SVL = 55 mm ± 4.1 SD, range = 48–63 mm), and three subadult males (mean SVL = 41 mm ± 1.0 SD, range = 40–43 mm in the herpetology collection of the Natural History Museum of Los Angeles County (LACM) were examined for reproductive activity. All were collected May 1982 from Maricopa County (LACM 134498, 134500, 134503, 134504, 134506) and Pinal County (LACM 134478–134480, 134483–134489, 134491–134493, 134495–134497).

Ovaries and testes were histologically examined. Tissues were embedded in paraffin, histological sections were cut at 5 µm and stained with hematoxylin followed by eosin counterstain. Histology slides were deposited in LACM.

Xantusia bezyi males larger than 48 mm SVL were undergoing spermiogenesis (lumina of the seminiferous tubules are lined by sperm or metamorphosing spermatids). Three smaller males measuring 40 mm (LACM 134996), 41 mm (LACM 134497) and 42 mm SVL (LACM 134495), all from May, exhibited early recrudescence (seminiferous tubules contain ca. 4 layers of spermatogonia and primary spermatocytes) and were considered to be subadults.

Seven of eleven females were undergoing yolk deposition (basophilic yolk granules in the ooplasm) for a litter of 1–2 (mean litter size = 1.6 ± 0.53) that likely would have been produced in the fall. The smallest reproductively active female (LACM 134488) measured 53 mm SVL and contained two yolking follicles, As is typical for other xantusiid lizards (Goldberg and Bezy 1974. Herpetologica 30:350–360; Goldberg 2013. Sonoran Herpetol. 26:9–11), not all mature females reproduce each year. Thus, LACM 134056 (SVL = 48 mm), collected in May could have been a mature female that was not breeding.

In conclusion of this investigation, *X. bezyi* is a spring breeder with one to two young produced likely in early fall. Timing of events in the reproductive cycle of *X. bezyi* appear to be similar to the congeners *X. riversiana* (Goldberg and Bezy 1974, *op. cit.*), *X. henshawi* (Lee 1975. Trans. San Diego Soc. Nat. Hist. 17:259–278; Goldberg 2013, *op. cit.*), and *X. vigilis* (Miller 1948. Univ. California Publ. Zool. 47:197–213; Zweifel and Lowe 1966. Am. Mus. Novitat. 2247:1–57).

We thank G. Pauly (LACM) for permission to examine *X. bezyi*.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **ROBERT L. BEZY,** Section of Herpetology, Natural History Museum of Los Angeles County, Los Angeles, California 90007, USA (e-mail: robertbezy@gmail.com).

XANTUSIA BOLSONAE **(Bolsón Night Lizard). REPRODUCTION.** *Xantusia bolsonae* is known from two localities in the southern Chihuahuan Desert of Durango, Mexico (Webb 1970. Contrib. Sci. 194:1–10; Flores-Villela et al. 1990. Herpetol. Rev. 21:97). In this note we provide information on the timing of female *X. bolsonae* reproduction.

Eight *X. bolsonae* consisting of six adult females, mean SVL = 53.3 mm ± 3.0 SD, range = 48–57 mm, one sub-adult of indeterminate sex, SVL = 34 mm, and one neonate, SVL = 28 mm, in the herpetology collection of the Natural History Museum of Los Angeles County (LACM) were examined for reproductive activity: LACM 116260, 136791, 136792 (May 1975); LACM 76156, 76158, 76159 (September 1971); LACM 106805, 106806 (September 1972); all from the vicinity of Pedriceña, Durango, Mexico.

The specimens (except for the neonate) previously had been opened for the purposes of karyotypic study. Ovaries from the three September females were histologically examined. Tissues were embedded in paraffin, histological sections were cut at 5 µm and stained with hematoxylin followed by eosin counterstain. Histology slides were deposited in LACM. No histology was done on the embryos.

Two females from May contained developing embryos with visible eyes, LACM 136791 (SVL = 57 mm) and LACM 136792 (SVL = 53 mm). LACM 116260 from May (SVL = 55 mm) contained one oviductal egg with no embryo visible. We arbitrarily considered LACM 106805 (SVL = 48 mm) from September as an adult, although we could not determine if parturition had occurred. All September females contained quiescent ovaries with no yolk deposition in progress.

In summary, the presence of well-developed embryos in *X. bolsonae* in May suggests that young are born in late spring to early summer. Thus, the female reproductive cycle of *X. bolsonae* approximates that of the sympatric *X. extorris* (Webb 1965. Amer. Mus. Novitat. 2231:1–16), to which molecular data suggest it is closely related (Noonan et al. 2013. Mol. Phylogen. Evol. 69:109–122) and differs from that of the morphologically similar *X. henshawi* in which parturition occurs in September to October (Lee 1975. Trans. San Diego Soc. Nat. Hist. 17:259–278; Goldberg 2013. Sonoran Herpetol. 26:9–11).

We thank G. Pauly (LACM) for permission to examine *X. bolsonae*.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **ROBERT L. BEZY,** Section of Herpetology, Natural History Museum of Los Angeles County, Los Angeles, California 90007, USA (e-mail: robertbezy@gmail.com).

***XANTUSIA EXTORRIS* (Durango Night Lizard). REPRODUCTION.** *Xantusia extorris* was described from Durango, Mexico by Webb (1965. Amer. Mus. Novitat. 2231:1–16). It is currently known from Durango and Zacatecas (Baker et al 1981. Southwest. Nat. 25:568–569). Webb (*op. cit.)* reported one or two embryos were present in all females > 38 mm from May and estimated that offspring are born in late May or early June. The purpose of this note is to provide additional information on the timing of events in the *X. extorris* reproductive cycle.

Sixteen females (mean SVL = 37.5 mm ± 2.1 SD, range = 33–42 mm) and six males (SVL = 34.8 mm ± 1.7 SD, range = 33–38 mm) of *X. extorris* from the herpetology collections of the Natural History Museum of Los Angeles County (LACM), Los Angeles, California, USA and the University of Arizona (UAZ), Tucson, Arizona, USA from Durango, Mexico, vicinity of Pedricena (25.1000°N, 103.7833°W, 1325 m elevation) were borrowed: LACM:106802, 116263, 116265–116268; UAZ: 17404, 17405, 17408, 17570, 17563, 17564, 17568, 17569, 17572–17576, 17580–17582. The specimens were collected 1965 to 1975.

Testes were histologically examined. Tissues were embedded in paraffin, histological sections were cut at 5µm and stained with hematoxylin followed by eosin counterstain. Histology slides were deposited in LACM and UAZ.

All six males contained regressed testes in which the seminiferous tubules were very small and contained primarily spermatogonia. It is possible they were all subadults.

Mean litter size for fifteen females with oviductal eggs from April to May was 1.4 ± 0.51 SD, range = 1–2. One female (LACM 116267, SVL = 33 mm) from May contained quiescent ovaries (no yolk deposition) and was either a subadult or an adult that was not breeding. The smallest reproductively active female (UAZ 17581) measured 34 mm SVL, was collected during April and contained one oviductal egg. This is a new minimum size for reproductive activity in *X. extorris* females; Webb (*op. cit.*) reported the smallest gravid female measured 38 mm SVL. An embryo was externally visible in one oviductile female from May (LACM 116268). No eggs were dissected to ascertain the presence of embryos.

In summary, the presence of an embryo and oviductal eggs in female *X. extorris* from April and May suggests that young are born in late spring to early summer confirming the observations of Webb (*op. cit.*). The presence of regressed testes in males from April and May differs strikingly from the reproductive cycle of the spring breeding *X. vigilis* (Miller 1948. Univ. California Publ. Zool. 47:197–213) and is suggestive that *X. extorris* may breed in fall or winter. Our data indicate the timing of events in the reproductive cycles of *X. extorris* and *X. bolsonae* (Goldberg and Bezy 2014. Herpetol. Rev. 45:509–510) are similar. Moreover, molecular data (Noonan et al. Mol. Phylogen. Evol. 69:109–122) suggest these two species are closely related.

We thank G, Bradley (UAZ) and Greg Pauly (LACM) for permission to examine *X. extorris*.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **ROBERT L. BEZY,** Section of Herpetology, Natural History Museum of Los Angeles County, Los Angeles, California 90007, USA (e-mail: robertbezy@gmail.com).

***XANTUSIA WIGGINSI* (Wiggins' Night Lizard). REPRODUCTION.** *Xantusia wigginsi* is found from southern California through Baja California to northern Baja California Sur (Sinclair et al. 2004. Amer. Nat. 163:396–414; Leavitt et al. 2007. Mol. Ecol. 16:4455–4481; Backlin and Fisher 2011. Herpetol. Rev. 42:392). We present the first information on litter size and the timing of events in the reproductive cycle of the species.

Nineteen *X. wigginsi* consisting of three adult males (mean SVL = 34 mm ± 2.0 SD, range = 32–36 mm); thirteen adult females (mean SVL = 36.6 mm ± 2.6 SD, range = 34–43 mm), one subadult male (SVL = 31.0 mm SVL) and two subadult females (SVL = 33.0 mm) in the herpetology collection of the Natural History Museum of Los Angeles County (LACM) were examined from localities between 27.59°N and 31.33°N in Baja California (LACM 3761, 26142, 36569, 62245, 101211, 101213–01224, 101330) and Baja California Sur (LACM 126139). The specimens had been collected between 1954 and 1977.

Ovaries and testes were histologically examined. Tissues were embedded in paraffin, histological sections were cut at 5 µm and stained with hematoxylin followed by eosin counterstain. Histology slides are deposited in LACM.

Two males from May were undergoing sperm formation (spermiogenesis) in which the lumina of the seminiferous tubules were lined by sperm or clusters of metamorphosing spermatids. One male from June was undergoing late spermiogenesis in which the number of cell layers in the germinal epithelium was reduced. The smallest reproductively active male (spermiogenesis) measured 32 mm SVL (LACM 36569) and was from May. One male (LACM 101221) from April (SVL = 31 mm) exhibited testicular recrudescence (proliferation of germ cells for the next period of spermiogenesis). It was classified as a juvenile as it is not known when spermiogenesis would have commenced,

Four stages were observed in the ovarian cycle: 1) quiescent, no yolk deposition; 2) early yolk deposition (vitellogenic granules) in ooplasm; 3) enlarged ovarian follicles (> 4 mm); 4) embryo present (Table 1). Litter size for five females was 1.0 for each. The two smallest reproductively active females (early yolk deposition) each measured 34 mm SVL (LACM 101211, 101225) and were from April. Two April females (each 33 mm SVL) exhibited quiescent ovaries (LACM 101217, 101220) and were classified as juveniles.

In summary, *X. wigginsi* is a spring breeder with young produced in early fall. Timing of events in the reproductive cycle appears similar to *X. riversiana* (Goldberg and Bezy 1974. Herpetologica 30:350–360; *X. henshawi* (Lee 1975. Trans. San Diego Soc. Nat. Hist. 17:259–278; Goldberg 2013. Sonoran Herpetol. 26:9–11) and *X. vigilis* (Miller 1948. Univ. California Publ. Zool. 47:197–213; Zweifel and Lowe 1966. Am. Mus. Novitat. 2247:1–57). Although the sample is limited, *X. wigginsi* may have the smallest litter size (1.0) in the genus.

TABLE 1. Monthly stages in the ovarian cycle of 13 *Xantusia wigginsi.*

Month	N	Quiescent	Early yolk deposition	Enlarged follicles > 4 mm	Embyros
March	1	1	0	0	0
April	9	2	5	2	0
June	2	0	0	2	0
August	1	0	0	0	1

We thank G. Pauly (LACM) for permission to examine *X. wigginsi*.

STEPHEN R. GOLDBERG, Department of Biology, Whittier College, Whittier, California 90608, USA (e-mail: sgoldberg@whittier.edu); **ROBERT L. BEZY,** Section of Herpetology, Natural History Museum of Los Angeles County. Los Angeles, California 90007, USA (e-mail: robertbezy@gmail.com).

***ZOOTOCA VIVIPARA* (Common Lizard). ABNORMAL ACTIVITY.** An activity period of *Zootoca vivipara* in St. Petersburg, Russia region spans about five and a half months. This cold-tolerant species is active from mid-April to late September–early October. The earliest record of spring activity within the St. Petersburg region is 3 April, latest autumn record on surface is 11 October. Populations of this species inhabit slopes of Pulkovo Heights that are covered partly by agriculture and partly by secondary mixed forest.

November of 2013 in St. Petersburg was unusually warm. The average monthly temperature at 2 m above ground was 4.2°C. During two weeks of observations the average daily air temperature was 4.9°C; minimum value 0.0°C; maximum value 8.2°C for period 10–24 November 2013. Maximum air temperature for this period was registered on 17 November (http://rp5.ru/).

On 17 November during a visit to the Pulkovo Heights, St. Petersburg, Russia (59.7722355°N, 30.3190041°E), I found one freshly killed adult male *Z. vivipara* out of its winter burrow. The dead lizard was found on the road along a garden on the western slope near habitat typically used by this lizard. The lizard (now stored in Zoological Institute, ZISP 27409) had been very recently killed on the road by vehicle. On this date the air temperature reached 8.2°C, humidity 53–83%, wind NW, wind speed 7 m/c, cloud coverage 70–80%, stratocumulus.

This unprecedented record of atypical activity in this species can be explained by the abnormally warm autumn season in 2013 in eastern Europe.

KONSTANTIN D. MILTO, Department of Herpetology, Zoological Institute, Universitetskaya emb., 1, St. Petersburg, 199034, Russia; e-mail: coluber@zin.ru.

SQUAMATA — SNAKES

***AGKISTRODON PISCIVORUS* (Cottonmouth). DIET.** *Agkistrodon piscivorus* is an abundant semiaquatic pitviper endemic to the southeastern United States. While *A. piscivorus* is a highly generalized opportunist that preys upon a wide variety of taxa, fish and amphibians are the most frequent prey (Ernst and Ernst 2003. Snakes of the United States and Canada, Smithsonian Books, Washington, DC. 668 pp.). On 30 June 2013, at approx. 1500 h, we collected a juvenile *A. piscivorus* along the bank of Pond Creek, Conecuh National Forest, Covington Co., Alabama, USA (31.09768°N, 86.53458°W; datum WGS84). The snake's body was distended due to a large prey item. After manual palpation, the snake regurgitated the remains of an adult *Lithobates grylio* (Pig Frog). The frog was identifiable but in an advanced stage of digestion, so no attempt was made to collect it. *Agkistrodon piscivorus* is a known predator of *Lithobates* species, including *L. catesbeianus, L. clamitans, L. palustris,* and *L. sphenocephalus* (Ernst and Ernst, *op. cit.*). However, to our knowledge this represents the first published record of *L. grylio* in the diet of *A. piscivorus.*

Funding was provided by a Penn State Office of Undergraduate Education Summer Discovery Grant to Mark Herr and a National Science Foundation Grant (IOS-1051367, DEB-0949483) to Tracy Langkilde.

MARK W. HERR (e-mail: mwh5426@psu.edu), Department of Biology, The Pennsylvania State University, 208 Mueller Laboratory, University Park, Pennsylvania 16801, USA; **SEAN P. GRAHAM**, Department of Biology, University of Findlay, 1000 N. Main St., Findlay, Ohio 45840, USA.

***AGKISTRODON PISCIVORUS CONANTI* (Florida Cottonmouth). DIET and PHENOTYPE.** *Agkistrodon piscivorus conanti* is a semi-aquatic pit viper native to the southeastern United States (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, Washington, D.C. 668 pp.). On 25 June 2013, a nuisance female amelanistic *A. p. conanti* (total length = 58.5 cm; 250 g) was removed from a residential property in Flagler Co., Palm Coast, Florida, USA by staff from the Central Florida Zoo, Seminole Co., Lake Monroe, Florida, USA. The snake was subsequently transported to the Central Florida Zoo on the day of capture. During physical exam, symmetrical internal lumps could be seen throughout the body (Fig. 1), and a large, unknown item inside the snake could be felt via palpation. Due to health concerns for the *A. p. conanti*, it was ultimately decided that surgery was necessary to remove the object that appeared to be lodged in its stomach.

A *Pantherophis guttatus* (Red Cornsnake; total length = 71 cm; 100 g) was surgically-removed from the stomach of the *A. p. conanti* on 30 June 2013. Despite being ingested, the *P. guttatus* was largely intact following several days after capture and was becoming necrotic. While *A. piscivorus* has been known to feed on several snake species (Gloyd and Conant 1990. Snakes of the *Agkistrodon* Complex. Society for the Study of Amphibians and Reptiles, St. Louis, Missouri. 620 pp.; Ernst and Ernst, *op. cit.*), to our knowledge this is the first recorded account of *P. guttatus* in the diet of the species. The *A. p. conanti* has been added to the reptile collection at the Central Florida Zoo.

FIG. 1. A postprandial amelanistic *Agkistrodon piscivorus conanti*, that had consumed a *Pantherophis guttatus* in Flagler Co., Florida, USA.

We thank James Bogan of The Critter Fixer of Central Florida for assistance and Michael Ravesi for comments on the manuscript.

SASHA J. TETZLAFF (e-mail: tetzsj01@ipfw.edu), Department of Biology, Indiana University-Purdue University Fort Wayne, 2101 East Coliseum Boulevard, Fort Wayne, Indiana 46805, USA; **DAVID L. TETZLAFF** (e-mail: davidt@centralfloridazoo.org), **MICHELLE SCHOENBECK**, and **NICK CLARK**, Central Florida Zoo, P.O. Box 470309 North Highway 17-92, Lake Monroe, Florida, USA.

***BOTHROPS ASPER* (Fer-de-lance). DIET.** Members of the genus *Bothrops* are diet generalists (Martins et al. 2002. *In* Schuett et al. [eds.], Biology of the Vipers, pp. 307–328, Eagle Mountain Publishing, Eagle Mountain, Utah). Juvenile *B. asper* eat arthropods, frogs, and lizards while adults also consume birds, rodents, and medium-sized mammals (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. Univ. Chicago Press, Illinois. 934 pp.; Sasa et al. 2009. Toxicon 54:904–922). Here we report the first observation of any *Bothrops* consuming a caecilian.

On 15 April 2013, a *Bothrops asper* was observed consuming a *Dermophis parviceps* (Slender Caecilian) on a dirt/mud road bordered by mid-elevation primary forest at Rara Avis Rainforest Reserve bordering Braulio Carillo National Park, Sarapiqui, Costa Rica (10.28201°N, 84.04577°W, datum WGS84; elev. 738 m). At 0725 h MAJ and JRS encountered the *B. asper* (total length = 758 mm) lying across a shallow pool of water in the road. Based on size and lack of a yellow caudal tip the snake could have been a juvenile female or adult male (Savage, *op. cit.*). A nearly immobile caecilian, *D. parviceps*, (SVL = 371 mm) was semi-coiled, also in the shallow pool, 40 cm from the snake. The caecilian's head was first below the surface of the water but rose above the surface during the observation, indicating that this was not a case of scavenging. While no strike by the snake was observed, the caecilian had likely been envenomated. The authors returned to the location at 0830 h. At this point the snake was lying by the side of the pool and the caecilian was coiled in the pool (Fig. 1). The snake removed the caecilian from the water 7 min after the last apparent movement by the caecilian. The caecilian was folded in a U-shape, one-fifth of the way down the body. After 31 min the snake proceeded to consume the caecilian starting at the fold in the body (Fig. 2). The consumption of the caecilian took 21 min. The entire predation event lasted longer than 2.25 h. The presence of the authors and a group of tourists may have increased the duration of the predation event.

FIG. 1. *Bothrops asper* prior to consuming the (presumably) envenomated *Dermophis parviceps*.

FIG. 2. *Bothrops asper* consuming a *Dermophis parviceps* starting at a point one-fifth of the way down the body instead of directly from the head of the caecilian.

This observation is notable for two reasons. First, the novel observation of consumption of a fossorial caecilian by a terrestrial *B. asper*. Second, the snake did not consume the caecilian directly from the head as is often noted when elongate predators eat elongate prey (Jackson et al. 2004. Zoology 107:191–200). It is unclear whether this was a rare event, representing opportunistic predation by *B. asper*, or whether caecilians make up a regular part of their diet.

MEGAN A. JONES, Division of Biological Science, Florida State University, 319 Stadium Dr., Tallahassee, Florida 32306-4295, USA (e-mail: majones@bio.fsu.edu); **JASON R. STRAKA**, Parks Canada Agency, Wood Buffalo National Park, Box 38, Fort Chipewyan, Alberta, Canada, T0P 1B0 (e-mail: jstrak@gmail.com); **KIMIKO KAYANO** (e-mail: kayano_kimiko806z@yahoo.com).

***BOTHROPS ASPER* (Terciopelo). DIET.** The genus *Bothrops* is widely distributed in South America and Central America (Campbell and Lamar 2004. The Venomous Reptiles of the Western Hemisphere. Comstock Publ., Ithaca, New York. 870 pp.). The species belonging to this genus are generalists and feed mostly on insects, frogs, lizards, snakes, birds and mammals (Schuett 2002. Biology of the vipers. Eagle Mountain, Utah. 580 pp.). However, references regarding wild prey are scarce.

At 1100 h on 18 June 2013 an adult female *Bothrops asper* (total length = 1780 mm) was found in a patch of tropical evergreen forest in Flavio Alfaro, Ecuador (0.390°S, 79.849°W, datum WGS84; elev. 427 m). The snake had been killed by farmers and was taken to the laboratory where it was dissected. In the stomach we found the whole body of a rat (*Proechimys semispinosus)* in an advanced stage of digestion. This rat was previously cited as prey of *B. asper* in Costa Rica (Sasa et al. 2009. Toxicon 54:904–922). In the intestine we found porcupine quills from *Coendou rothschildi* (Fig. 1) never before reported as prey of *B. asper*. We thank Víctor H. Luja and Rogelio Cedeño for comments on this note.

***COLUBER* (=*MASTICOPHIS*) *BILINEATUS* (Sonoran Whipsnake). DIET.** The diet of the swift-moving *Coluber bilineatus* has been reported to include birds, small mammals, lizards, snakes, and frogs (Stebbins 2003. A Field Guide to Western Reptiles and Amphibians, 3rd ed. Houghton Mifflin Co., Boston, Massachusetts. 533 pp.) To our knowledge, the only report of a *C. bilineatus* preying upon a frog or any amphibian, is an adult *Lithobates yavapaiensis* consumed by a "large" adult *C. bilineatus* in Buehman Canyon, Pima Co., Arizona (Bezy and Enderson 2003. Son. Herpetol. 16:17). On 18 Sep 2013 at 1608 h, JCR heard a thrashing and a frog squawking in cattails at the edge of a flooded mine adit in Middlemarch Canyon, Dragoon Mountains, Cochise Co., Arizona, USA (31.881429°N 109.953556°W, datum WGS84; elev. 1698 m). An approximately 1.2 m (total length) *C. bilineatus* emerged from the cattails with an adult (~70 mm SVL) *L. chiricahuensis* in its mouth. The snake had grasped the frog by the left hindquarters, but quickly adjusted so the frog's head was in its mouth. JCR approached for better pictures (Fig. 1; UAZ 57569-PSV), and at 1612 h the snake, with the frog still in its mouth, disappeared into grasses at the edge of the pond, or into the water.

JAMES C. RORABAUGH, P.O. Box 31, Saint David, Arizona 85630, USA (e-mail: jrorabaugh@hotmail.com); **CRISTINA A. JONES**, Arizona Game and Fish Department, 5000 W. Carefree Hwy, Phoenix, Arizona 85086-5000, USA.

***COLUBER* (= *MASTICOPHIS*) *FLAGELLUM* (Coachwhip). DIET / OPHIOPHAGY.** *Coluber flagellum* is known to take a variety of prey items including snakes (Beaman and Basey 2011. Herpetol. Rev. 42:437). Here we report a snake as a prey item not previously documented for *C. flagellum*.

On 27 April 2012, a *C. flagellum* was encountered ingesting a live *Crotalus ruber* (Red Diamond Rattlesnake; Fig 1) in Sycamore Canyon Wilderness Park, Riverside, Riverside Co., California, USA (33,937083°N, 117.317605°W; datum WGS 84). The *C. ruber* had five rattle segments, including the button, which corresponds to an adult size within the range of 60–80 cm snout-vent length (N = 89; Dugan 2011. Ph.D. Dissertation, Loma Linda University, Loma Linda, California). Digital images were deposited in the herpetological collections of the Natural History Museum of Los Angeles County (LACM PC 1605, 1607)

DUGAN**, NOREAS Inc., Irvine, California 92618, USA (e-mail: eric.dugan@noreas-inc.com); **WILLIAM K. HAYES**, Department of Earth and Biological Sciences, Loma Linda University, Loma Linda, California 92350, USA (e-mail: whayes@llu.edu).

FIG. 1. *Coluber bilineatus* with adult *Lithobates chiricahuensis* in its mouth, Cochise Co., Arizona, USA.

FIG. 1. *Coluber flagellum* feeding on *Crotalus ruber*, Riverside Co., California, USA.

***CONTIA TENUIS* (Sharp-tailed Snake). PREDATION.** *Latrodectus mactans* (Black Widow) is known to prey on a variety of organisms, including snakes (Klauber 1940. Trans. San Diego Soc. Nat. Hist. 9:87–162; Jones et al. 2011. Herpetol. Rev. 42:440–441). This is the first arachnid predation documented for *C. tenuis*. On 1 July 2013, at 0645 h, one of us (NGT) observed a snake suspended in the web of a female *L. mactans* beneath a parked vehicle at 4519 Plantation Drive, Fair Oaks, California, USA (34.6480310°N, 121.2995338°W, datum WGS 84; Fig. 1). The spider was positioned to the side of the snake's head, and a pin-sized drop of blood was visible near the snake's mouth. It appeared that the spider was in the process of consuming the snake. Digital images were deposited in the herpetological collections of the Natural History Museum of Los Angeles County (LACM-PC 1668–1672).

FIG. 1. Adult female *Latrodectus mactans* (Black Widow) feeding on *Contia tenuis*, Fair Oaks, California, USA.

KENT R. BEAMAN, Section of Herpetology, Natural History Museum of Los Angeles, Los Angeles, California 90007, USA (e-mail: heloderma@roadrunner.com); **NATE G. TUCKER**, 4519 Plantation Dr., Fair Oaks, California 95628, USA.

***CROTALUS ANGELENSIS* (Isla Ángel de la Guarda Rattlesnake). DIET and PREDATION.** On 23 June 2012 we found a deceased adult *Crotalus angelensis* (Total length = 770 mm) inside the desiccated corpse of an adult *Lampropeltis getula* (Common Kingsnake; Total length = 1130 mm) on the southwestern coast of Isla Ángel de la Guarda (29.140250°N, 113.297983°W; datum WGS 84) in the Gulf of California, Baja California, Mexico (Fig. 1). It appeared that the kingsnake had died while consuming the rattlesnake because 260 mm of the posterior was emerging from the kingsnake's mouth, but the timing and cause of death

FIG. 1. Deceased and dessicated *Lampropeltis getula* that died while consuming an adult *Crotalus angelensis;* note mass of feathers inside the *Crotalus angelensis*.

are unknown. A mass of black feathers from an unidentified bird was embedded in the stomach of the rattlesnake, the first known record of this species consuming a bird. Little is known regarding the predators and prey of *C. angelensis*, although *Sauromalus hispidus* (Spiny Chuckwalla) has been recorded as a diet item (Grismer 2002. Amphibians and Reptiles of Baja California, Including its Pacific Islands and the Islands in the Sea of Cortés. Univ. California Press, Berkeley. 339 pp.), and insular populations of the closely related Speckled Rattlesnake (*C. mitchellii*) are known to prey upon *Uta stansburiana* (Side-blotched Lizard) and *S. hispidus* (Meik et al. 2012 Herpetol. Rev. 43:556–560). *Lampropeltis getula* is known to prey upon rattlesnakes elsewhere in its range, although its diet has not been studied on Isla Ángel de la Guarda. Geo-referenced photographs are vouchered at the San Diego Natural History Museum, San Diego, CA (SDSNH_HerpPC_05225–05232).

We thank the Comisión Nacional de Áreas Naturales Protegidas (CONANP) for granting permits to visit Isla Ángel de la Guarda, the Secretaría de Medio Ambiente y Recursos Naturales (SEMARNAT) for granting permits (Ofico. Num. SGPA/DGVS/01239/12) to collect lizard specimens in Mexico, and Brad Hollingsworth for vouchering our photographs.

***CROTALUS ATROX* (Western Diamond-backed Rattlesnake). RAIN HARVESTING BEHAVIOR.** To date, few episodes of the rattlesnake *Crotalus atrox* obtaining water from rain, sleet, and snow in arid habitats have been reported (Repp and Schuett 2009. Southwest. Nat. 53:108–114). However, those episodes have been observed only in late winter; that is, during the inactive season, and only from individuals inhabiting the Sonoran Desert. Herein, we report the first observation of a *C. atrox* harvesting rainwater during the active season (summer) in the northern Chihuahuan Desert.

On 28 August 2010, at 1640 h on a cloudy and breezy afternoon, an adult male *C. atrox* (SVL = 1000 mm; tail length = 80

FIG. 1. Adult male *Crotalus atrox* harvesting rainwater from a pool formed between its coils in late August at Indio Mountains Research Station, Hudspeth Co., Texas.

mm; 689.9 g) fitted with a Holohil Ltd. SB-2 transmitter was radiotracked at Indio Mountains Research Station (IMRS), Hudspeth Co., Texas, USA (30.769358°N, 105.009242°W, datum WGS 84; 1240 m elev.), as part of an ongoing study. Initially the rattlesnake was observed resting in a tightly coiled position at the base of a grass (*Aristida purpurea*) of an alluvial slope (10°). A few minutes later; as a brief rain was taking place in the area, we returned to examine if the snake's behavior was affected by the rain. To our surprise, we found the rattlesnake located in the same location but with its body in a loose coil position with its last two coils flattened dorso-ventrally and tightly in contact with each other (Fig. 1). As rain progressed, a water pool was formed between the latter coils and consequently with the head facing down the rattlesnake proceeded to drink rainwater for ca. 20 min. The latter behavior was clearly detected by the slight rhythmic movements of its jaw musculature. After the sporadic rain episode was over, the rattlesnake continued harvesting the remaining rainwater from its body and then went back to the same resting position until dusk. Rain harvesting during the active season has been observed in *C. molossus* at IMRS (Mata-Silva et al. 2012. Herpetol. Rev. 43:145-146).

VICENTE MATA-SILVA (e-mail: vmata@utep.edu), and **JERRY D. JOHNSON** (e-mail: jjohnson@utep.edu), Department of Biological Sciences, University of Texas at El Paso, El Paso, Texas 79968, USA.

***DROMICODRYAS BERNIERI* (Bernier's Striped Snake). DIET.** Most Malagasy snake species appear to feed primarily on frogs and lizards (Mercurio et al. 2006. Salamandra 42:181-183). *Dromicodryas bernieri* was thought to be strictly saurophagous (Cadle 2003. *In* Goodman and Benstead [eds.], Natural History of Madagascar, pp. 997–1004. Univ. Chicago Press, Chicago; Gehring 2006. Zeitschrift des Kölner Zoo - Heft 49:127–141) but was recently found to feed on amphibians as well (Gandola et al. 2013. Herpetol. Rev. 44:689-690). Here, predation on *Chalarodon madagascariens* by *D. bernieri* is described.

In the late afternoon on 16 December 2007, a *D. bernieri* was observed foraging in heavily degraded spiny forest in Ifaty, Madagascar (23.070806°S, 43.364108°E, datum: WGS84). The specimen was chasing an adult male *Chalarodon madagascariensis*, moving rapidly with its anterior body raised above the ground. Due to the observer, the snake ceased the hunt and fled. On 18 December 2007 at 0910 h, a second *D. bernieri* was found

FIG. 1. *Dromicodryas bernieri* feeding on a *Chalarodon madagascariensis* in Ifaty, Madagascar.

constricting and swallowing a *C. madagascariensis* (Fig. 1). While constricting, the snake did not keep its prey in its mouth and raised its head upwards to observe the surroundings. Constriction continued for approximately 5 min after which the prey was swallowed, head first, in approximately 10 min.

I thank V. J.T. Loehr for reviewing the first draft of this correspondence.

RICHARD P.J.H. STRUIJK, Reptile, Amphibian & Fish Conservation Netherlands, Natuurplaza, Toernooiveld 1, 6525 ED Nijmegen, the Netherlands; e-mail: r.struijk@ravon.nl.

***ECHIS COLORATUS* (Palestine Saw-scaled Viper). REPRODUCTION.** *Echis coloratus* is known to occur in Egypt east of the Nile, Israel south to western and southern Arabian Peninsula where it frequents rocky ground (Phelps 2010. Old World Vipers A Natural History of the Azemiopinae and Viperinae. Edition Chimaira, Frankfurt am Main. 558 pp.). Up to 10 eggs are laid in August (Bar and Haimovitch 2011. A Field Guide to Reptiles and Amphibians of Israel. Pazbar LTD 1989, Herzilya Israel. 245 pp.); eggs are laid about 75 days after copulation (Phelps *op. cit.*). The purpose of this note is to present data on the monthly events in the testicular cycle and the minimum size for maturity of males.

A sample of ten *E. coloratus* males consisting of eight adults (mean SVL = 545.5 mm ± 67.9 SD, range = 465–663 mm) and two subadults (mean SVL = 447 mm ± 15.6 SD, range = 436–458 mm) collected 1957 to 2012 and deposited in the Natural History Collections of Tel Aviv University (TAUM), Tel Aviv, Israel was examined. Specimens examined by region were: A'rava Valley (TAUM 6112, 6113, 9016), Central Negev (TAUM 2821, 15901), Dead Sea Area (TAUM 4522, 5188, 14116, 16186), Shomeron (TAUM 16488). The left testis was removed, embedded in paraffin and cut into sections of 5 µm. Histology slides were stained with Harris' hematoxylin followed by eosin counterstain and were deposited in TAUM.

Three stages were observed in the monthly testicular cycle (Table 1), 1) regression, the germinal epithelium in the seminiferous tubules is reduced to a few layers, consisting of spermtogonia and sertoli cells; 2) recrudescence, there is a proliferation of germ cells for the approaching period of sperm formation. Primary spermatocytes predominate; 3) spermiogenesis, the lumina of the seminiferous tubules are lined by sperm or clusters of metamorphosing spermatids. The period of sperm production in spring (Table 1) fits within the ca. 75 days needed for

TABLE 1. Monthly stages in the testicular cycle of eight adult males of *Echis coloratus* from Israel.

Month	N	Regression	Recrudescence	Spermiogenesis
March	1	0	1	0
April	1	0	0	1
May	2	0	0	2
June	3	0	0	3
October	1	1	0	0

egg development (Phelps, *op. cit.*). The smallest mature male (spermiogenesis) measured 465 mm SVL (TAUM 6112) and was collected in June. Two other subadult males from June: 1) (TAUM 4552) SVL = 458 mm exhibited recrudescence and 2) (TAUM 6113) SVL = 436 mm exhibited regression.

I thank Shai Meiri (TAUM) for permission to examine *E. coloratus*, Erza Maza for facilitating the loan and the National Collections of Natural History at Tel Aviv University for providing *E. coloratus* for this study.

STEPHEN R. GOLDBERG, (e-mail: sgoldberg@whittier.edu), Natural History Museum of Los Angeles County, Herpetology Section, Los Angeles, California, USA.

***GERARDA PREVOSTIANA* (Gerard's Watersnake). REPRODUCTION.** Although *Gerarda prevostiana* is a fairly common species in coastal mangrove forests and adjacent mudflat habitats from western India to the Philippines (Murphy 2007. Homalopsid Snakes: Evolution in the Mud. Krieger Publ. Co., Malabar, Florida. 260 pp.) and Borneo (Das et al. 2013. Asian Herpetol. Rec. 4:76–78), little has been documented concerning reproduction.

FIG. 1. Adult female *Gerarda prevostiana* with clutch of five juveniles.

TABLE 1. Measurements of adult and five neonate *Gerarda prevostiana*, post-partum.

Animal ID	Mass (g)	SVL (mm)	Tail length (mm)
Adult female	29.52	399	58
Neonate1	2.70	145	25
Neonate2	2.93	158	25
Neonate3	2.69	155	24
Neonate4	2.35	148	26
Neonate5	2.71	145	28
Neonate average (SD)	2.68 (0.21)	150 (6)	26 (2)

On 16 November 2013 at approximately 2130 h, we collected a gravid female *G. prevostiana* at Pasir Ris Park, Singapore (01.378598°N 103.950738°E; datum: WGS 84). On 26 November 2013, the female gave birth to five offspring (Fig. 1; Table 1). The combined post-partum neonate mass was 13.38 g, which is 45.3% of the mass of the mother post-partum or 31.2% of the combined mass of adult and offspring. To our knowledge, this is the first description of relative clutch mass and intra-clutch variation in *G. prevostiana*. This work was conducted under NUS Institutional Animal Care and Use Committee (B01/11(A1)13) and National Parks Board of Singapore (NPRP10-095-2a) permission.

***LAMPROPELTIS GETULA* (Common Kingsnake). DIET.** *Lampropeltis getula* has long been known to prey on turtle eggs and "so addicted are they to this egg diet, that the natives consider that is a common happening to find snakes awaiting the egg deposition" (Wright and Bishop 1915. Proc. Acad. Nat. Sci. Phila. 67:107–192). Other reports of turtle egg-eating behavior by *L. getula* include a variety of turtle genera in the families Chelydridae, Kinosternidae, and Emydidae (Ernst and Ernst 2003. Snakes of the Unites States and Canada. Smithsonian Press, Washington, D.C. 668 pp.). *Terrapene carolina* have been mentioned as a possible species whose eggs are eaten, but no direct observation appears to have been recorded. Knight and Loraine (1986. Brimleyana 12:1–4) reported finding a female *L. getula* less than 1 m away from a nesting *T. carolina* with its head elevated from the ground and directed toward the nesting female turtle. It was probable, given the circumstances that this snake was intending to ingest eggs from this nest. Reported here is the first direct observation of *L. getula* preying on a *T. carolina* nest.

On 5 July 2012 at 1800 h I observed a female *T. carolina* nesting on my front lawn near Asheboro, in Randolph Co., North Carolina, USA. This turtle dug a shallow nest, deposited 3–4 eggs, covered the nest, and left the nesting site approximately 2 h later. On 9 July 2012, at 1058 h I observed a *L. getula* pushing its

FIG. 1. *Lampropeltis getula* digging into *Terrapene carolina* nest.

FIG. 2. *Lampropeltis getula* drinking contents of *Terrapene carolina* egg.

snout into the ground directly in the center of the nest (Fig. 1). The snake pushed dirt sideways toward the margins of the nesting hole for approximately 20 min in a similar digging method as reported by others (Posey 1973. Bull. Maryland Herpetol. Soc. 9:105; Brauman and Fiorillo 1995. Herpetol. Rev. 26:101–102). The snake then opened the top egg with its rostrum or teeth making several slits in the long axis of the egg shell, drank the contents of the egg (Fig. 2), and ingested the nearly empty egg shell whole. As best I could tell, the remaining two to three eggs were eaten whole and undamaged. Once the snake removed its head from the nest hole, it responded to my presence by orienting its head in my direction and flicking its tongue rapidly and then slowly crawled away from the nest. This entire predation event lasted from 1058 h to 1246 h.

I would like to thank Lori A. Williams and Joshua M. Kapfer for their comments on the manuscript, and James A. Spotila for his help with providing literature.

JOHN D. GROVES, North Carolina Zoological Park, 4401 Zoo Parkway, Asheboro, North Carolina 27205, USA; e-mail: johngroves2005@yahoo.com.

***LEPTOPHIS AHAETULLA* (Green Snake). DIET.** *Leptophis ahaetulla* is a medium-sized arboreal or semi-arboreal species that feeds primarily on hylid frogs and small lizards (Albuquerque et al. 2007. J. Nat. Hist. 41:1237–1243), and is widely distributed from southern Mexico to northern Uruguai (Oliver 1948. Bull. Am. Mus. Nat. Hist. 92: 157–280). On 11 June 2013, at 0930 h, on the Aiuaba Ecological Station (ESEC Aiuaba; 14.5911°S, 39.0655°W, datum WGS84; elev. ca. 466 m), state of Ceará, Brazil, an adult female *L. ahaetulla* (SVL = 890 mm) was observed perched on branches of a tree ca. 1.8 m from the ground, preying on an adult *Corythomantis greeningi* (SVL = 68.11 mm; 18 g). When first sighted, the snake was swallowing the head of the frog. The remaining ingestion process took 10 min (Fig. 1A), after which the snake was captured. The *L. ahaetulla* and the *C. greeningi* were deposited in the Coleção Herpetológica da Universidade Regional do Cariri (URCA-H 5539 and 5550, respectively; Fig. 1B). To the best of our knowledge, there are no records of predation of *C. greeningi* by *L. ahaetulla*.

Anurans and lizards consumed by *L. ahaetulla* are nocturnal and probably are captured by day when inactive (Martins and Oliveira 1999. Herpetol. Nat. Hist. 6:78–150; Albuquerque et al. 2005. Herpetol. Rev. 36:324–325; Solé et al. 2010. Salamandra 46:101–103). *Corythomantis greeningi* is distributed mainly in Caatinga biome and presents morphological features, such as a dermis that is co-ossified with the underlying cranial bones to

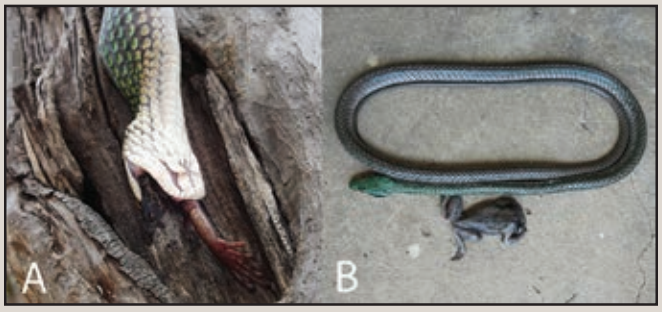

PHOTO BY HERIVELTO F. DE OLIVEIRA

form a unified structure (Trueb 1970. Univ. Kansas Publ. Mus. Nat. Hist. 18:547–716), and phragmotic behavior, that play important roles in defense (Jared et al. 2005. J. Zool. Lond. 265:1–8).

We are grateful to Conselho Nacional de Desenvolvimento Cientifico e Tecnológico (CNPq) for providing a fellowship to H.F.O. and for its financial support (process #551993/2011-1). ***LEPTOPHIS DIPLOTROPIS* (Pacific Coast Parrot Snake). DIET.** *Leptophis diplotropis* is endemic to Mexico and has been designated as a threatened species (SEMARNAT 2010. Norma Oficial Mexicana NOM-059-SEMARNAT-ECOL-2010. Protección

FIG 1. *Leptophis diplotropis* feeding on *Smilisca baudinii* at Universidad del Mar campus Puerto Escondido, San Pedro Mixtepec, Oaxaca, México.

ambiental-especies nativas de México de flora y fauna silvestre, Categorías de riesgo y especificaciones para su inclusión, exclusión o cambio-lista de especies en riesgo. Diario Oficial de la Federación 6 de marzo: pp. 1–78). This species ranges from Sonora along the pacific cost to the Isthmus of Tehuantepec in Oaxaca and into several central states, including Hidalgo, Morelos and Puebla (Berriozabal-Islas et al. 2012. Check List 8:1370–1372). It is arboreal and feeds primarily on frogs, lizards, snakes, and bird eggs (Canseco-Márquez and Gutiérrez-Mayén 2010. Anfibios y Reptiles de Valle de Tehuacán-Cuicatlán. México. BUAP & CONABIO. 302 pp.; Dixon and Lemos-Espinal 2010. Anfibios y Reptiles del Estado de Querétaro, México. Texas A&M University, UNAM, CONABIO. México. 428 pp.).

At 1550 h on 24 October 2013, on site of Universidad del Mar campus Puerto Escondido, San Pedro Mixtepec, Oaxaca, México (15.88942°N, 97.075757°W, datum WGS84; elev. 75 m) we observed a *L. diplotropis* attack and consume a *Smilisca baudinii* (Mexican Treefrog; Fig. 1) over 11 min. This is the first report of *S. baudinii* as a part of the diet of *L. diplotropis*.

***MICRELAPS MUELLERI* (Erdviper). REPRODUCTION.** *M. muelleri* is known from the Northern Negev of Israel, northward and also occurs in Syria, Jordan and Lebanon; it is a mildly venomous rear-fanged snake (Bar and Haimovitch 2011. A Field Guide to Reptiles and Amphibians of Israel. Pazbar LTD 1989, Herzliya, Israel. 245 pp.). There is a report that it is viviparous (Arbel [ed.] 1984. Reptiles and Amphibians, Vol. 5. Plants and Animals of the Land of Israel. An Illustrated Encyclopedia. Ministry of Defence and Publishing House for the Protection of Nature, Tel-Aviv, Israel. 248 pp.). The purpose of this note is to report a litter size of two for *M. muelleri*.

One *M. muelleri* female (SVL = 398 mm) deposited in the Tel Aviv University Museum (TAUM) as TAUM 1895, collected June 1955 in the Yizreel Valley Region (35.24166°N, 32.59638°E, datum WGS 84) was examined.

A ventral incision was made in the posterior third of the body. Two oviductal eggs were present, one in each oviduct. The eggs measured 20 × 4 mm and 24 × 4 mm, respectively. The eggs were not dissected, but externally there was no evidence of embryonic development. The ovaries were in quiescent condition (no yolk deposition). This is, to our knowledge, the first published record of a litter size of two for *M. muelleri*.

We thank Shai Meiri (TAUM) for permission to examine *M. muelleri*, Ezra Maza for facilitating the loan and the National Collections of Natural History at Tel Aviv University for providing *M. muelleri* for our examination.

GOLDBERG, Natural History Museum of Los Angeles County, Herpetology Section, 900 Exposition Boulevard, Los Angeles, California 90007, USA (e-mail: sgoldberg@whittier.edu); **ANAT FELDMAN,** Tel-Aviv University, Department of Zoology, Tel Aviv, 6997801 Israel (e-mail: anatfeld@post.tau.ac.il).

***OXYBELIS FULGIDUS* (Green Vine Snake). DIET.** *Oxybelis fulgidus* belongs to the group of Ophisoglyph Colubrids, with a neotropical distribution from México through América Central to Bolívia (Cisneros-Heredia and Touzet 2007. Herpetozoa 19:188-189). This species has generally been described as an opportunistic sit and wait predator, however they may also actively forage, feeding principally on lizards and birds, however small mammals are also consumed (Scartozzoni et al. 2009. S. Am. J. Herpetol. 4:81-89; Fraga et al. 2012. Herpetol. Rev. 43:495-496). This note contributes three new species to the list of food items in the diet of *O. fulgidus*, two birds and one lizard.

An *O. fulgidus* was observed predating a *Turdus leucomelas* (Pale-breasted Thrush) on 22 December 2008, an *Iguana iguana* (Green Iguana) on 02 January 2009, and a *Pitangus sulphuratus* (Great Kiskadee) on 24 December 2011 (Fig. 1); the first and third observations were in Parque Residencial Aquariquara I, Manaus, Amazonas, Brazil (3.084111°S, 59.961777°W; datum WGS84) and the second observation was in Praia da Lua, Manaus, Amazonas, Brazil (3.032555°S, 60.134111°W; datum WGS84). The only snake collected was from the third event, now INPA-H-32303 in

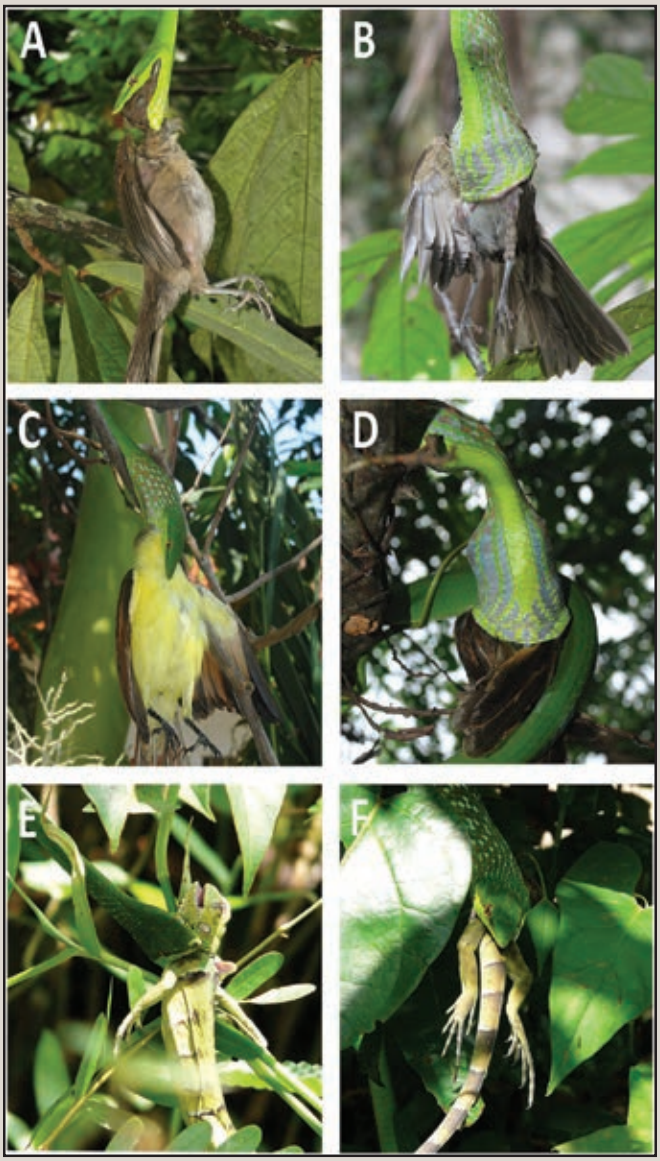

FIG. 1. *Oxybelis fulgidus* consuming their prey, *Turdus leucomelas* (A, B; Pale-breasted Thrush), *Pitangus sulphuratus* (C, D; Great Kiskadee), and *Iguana iguana* (E, F; Green Iguana).

the collection of Reptiles and Amphibians of Instituto Nacional de Pesquisas da Amazônia. The snake began to ingest the prey headfirst with *T. leucomelas* (Fig. 1A, B) and *P. sulphuratus* (Fig. 1C, D) the ingestion time for the latter took 2 h and 20 min while the iguana was swallowed in only 9 min (Fig. 1E, F). The great difference in ingestion time could be due to the difficulty for an ophisotglyph snake to envenomate the bird through the plumage, resulting in a longer processing time (Kardong 1982. Mem. Inst. Butantan 46:105–118).

We are grateful to Gersonval Leandro da Silva Monte who took the photo of the Green Iguana and "Rato" Rafael de Fraga, mentor in herpetology.

***PITUOPHIS RUTHVENI* (Louisiana Pinesnake). GROWTH RATES.** *Pituophis ruthveni* is a large-bodied constrictor endemic to western Louisiana and eastern Texas, USA, and is currently listed as a candidate species under the U.S. Endangered Species Act. Surveys suggest that the species has declined precipitously in recent decades and is now restricted to seven (several possibly recently extirpated) isolated populations (Rudolph et al. 2006. Southeast. Nat. 5:463–472). Although growth rates have been reported for radio-tracked *P. ruthveni* (Himes et al. 2002. J. Herpetol. 36:683–687), no information has been published regarding the growth rates of individuals without implanted transmitters. Here we report data on growth rates of *P. ruthveni* without radio transmitters and briefly compare them to individuals with transmitters.

Pituophis ruthveni were collected via a trapping effort conducted to monitor the species' populations. Data reported here were collected from 2007 to 2013 at multiple sites (Angelina National Forest, Angelina and Jasper counties, Texas; private property in Bienville Parish, Louisiana; and Ft. Polk, Vernon Parish, Louisiana). Snakes were implanted with PIT (Passive Integrated Transponder) tags and measured (SVL and total length to the nearest cm). All snakes were considered adults based on length. We included all recaptures that occurred at least 8 mo after initial capture (N = 8). Average monthly increases in SVL were highly variable ranging from 0 (for an individual monitored for only 8 months) to 0.49 cm/mo (Table 1). We observed a tendency for smaller animals to have higher growth rates than larger animals, a pattern noted by Himes et al. (*op. cit.*).

The growth rates reported in Table 1 are generally similar to those reported in Himes et al. (*op. cit.*). Mean growth rates (total length) of the adult animals in the Himes study were 0.26 cm/mo for males and 0.30 cm/mo for females. In this study mean growth rates (total length) were 0.28 cm/mo for males and 0.12 cm/mo for females. Females in this study were substantially larger than in Himes et al. (*op. cit.*), possibly explaining the lower growth rates. Growth rates of adult *P. ruthveni* without implanted transmitters in our study were generally similar to those of adult individuals with implanted transmitters (Himes et al., *op. cit.*), indicating transmitters may not be a major detriment to growth of *P. ruthveni*. However, other studies have shown negative effects of transmitters on mass gain in *Pantherophis obsoletus* (Weatherhead and Blouin Demers 2004. Wildl. Soc. Bull. 32:900–906) and survival in *P. ruthveni* (Rudolph et al. 1998. Herpetol. Rev. 29:155–156). Despite the lack of an obvious impact of transmitters on growth of *P. ruthveni*, researchers should remain cognizant of the potential for alteration of growth and behavior in snakes implanted with radiotransmitters.

***SISTRURUS MILIARIUS* (Pygmy Rattlesnake). DIET.** *Sistrurus miliarius* is known to take a variety of endothermic and ectothermic prey items including small rodents (*Microtus pinetorum*, *Oryzomys palustris*, *Peromyscus maniculatus*, *Reithrodontomys humulis*) and snakes (*Carphophis amoenus*, *Coluber constrictor*, *Diadophis punctatus*, *Nerodia* sp., *S. miliarius*, *Storeria dekayi*, *Thamnophis sauritus*, *T. sirtalis*, *Virginia valeriae*; Ernst and Ernst 2011. Venomous Reptiles of the United States, Canada, and Northern Mexico, Volume 1. Johns Hopkins Univ. Press, Baltimore, Maryland. 352 pp.). On 5 September 2013 at 0910 h, JRL and DJN captured an adult male *S. miliarius* (SVL = 39.2 cm; total length = 44.5 cm; 46 g) in a trap array located on

TABLE 1. Measurements and growth rates of *Pituophis ruthveni* from Texas and Louisiana, USA. (*) denotes an estimated SVL based on a regression model of unpublished *P. ruthveni* total lengths (TL) and snout–vent lengths (SVL) (N = 56).

the Camp Shelby Joint Forces Training Center, De Soto National Forest, Perry County, Mississippi, USA. The snake had recently fed as indicated by a large bolus in its stomach, and upon palpating, the snake regurgitated a male *Reithrodontomys fulvescens* (Fulvous Harvest Mouse). It is possible that the *R. fulvescens* was consumed in the trap, and therefore it is unknown how frequently *S. miliarius* will take this species as prey under natural circumstances. However, *R. fulvescens* is the second most abundant small mammal captured at this pitcher plant (*Sarracenia* sp.) wetland trap site (JRL, unpubl. data). On 2 December 2013 at 1130 h, JRL and ALS captured a juvenile male *S. miliarius* (SVL = 32.5 cm; total length = 37.1 cm; 27.9 g) basking in close proximity to this same trap array, and upon palpating, the snake regurgitated a female *Virginia striatula* (Rough Earthsnake). To the best of our knowledge these are the first documented occurrences of *R. fulvescens* and *V. striatula* in the diet of *S. miliarius*, and both represent novel food items for the genus *Sistrurus* (Ernst and Ernst, *op. cit.*).

JAMES R. LEE (e-mail: jlee@tnc.org), **DONALD J. NEWMAN III** (e-mail: dnewman@tnc.org), and **ABBY L. SINCLAIR** (e-mail: asinclair@tnc.org), The Nature Conservancy, Camp Shelby Joint Forces Training Center, CSJFTC-ENV; Building 6530, Camp Shelby, Mississippi 39407, USA.

***THAMNOPHIS COUCHII* (Sierra Gartersnake). PREDATION.** *Thamnophis couchii* is a highly aquatic species that inhabits streams, rivers, meadow ponds, and reservoirs of the Sierra Nevada of California from the Pit River drainage south to the western edge of the Tehachapi Mountains, with several populations east of the Sierran crest at Owens Valley, and along the Walker, Truckee, and Carson rivers in Nevada (Stebbins 2003. A Field Guide to Western Reptiles and Amphibians, 3rd ed. Houghton Mifflin Co., New York. 533 pp.; Rossman et al. 1996. The Garter Snakes: Evolution and Ecology. Univ. Oklahoma Press, Norman, 332 pp.). Although *T. couchii* is frequently encountered within its range, its only documented predators are *Buteo jamaicensis* (Red-tailed Hawk; Fitch 1949. Am. Midl. Nat. 41:513–579), *Coluber constrictor* (Yellow-bellied Racer) and *Diadophis punctatus* (Ring-necked Snake; Wiseman et al. 2007. Herpetol. Rev. 38:344–345). Herein, I report a previously undocumented predator of *T. couchii*.

On 10 September 2012 at 1030 h the posterior portion (ca. 7 cm) of a juvenile *T. couchii* was observed within the scat of a *Lontra canadensis* (River Otter) on the top of a boulder located ca. 3 m from the bank of the North Fork Feather River (Butte Co., CA.; 39.762892°N, 121.459782°W, datum WGS84; elev. 314 m), 0.8 km downstream of Bardee's Bar. The scat also contained the remains of introduced Signal Crayfish (*Pacifasticus leniusculus*). River Otters prey predominately on fish, crayfish, and other invertebrates but will also take amphibians and reptiles (Melquist et al. 2003. *In* Feldhamer et al. [eds], Wild Mammals of North America: Biology, Management, and Conservation, pp. 708–734. Johns Hopkins Univ. Press, Baltimore, Maryland). I thank Justin Garwood for his input and help tracking down literature sources.

KEVIN D. WISEMAN, Garcia and Associates, 2601 Mission Street, Suite 600, San Francisco, California 94110, USA; Department of Herpetology, California Academy of Sciences, 55 Music Concourse Drive, Golden Gate Park, San Francisco, California 94118, USA; e-mail: kwiseman@garciaandassociates.com.

***THAMNOPHIS SIRTALIS DORSALIS* (New Mexico Gartersnake). DIET.** Although avian nest predation by snakes has been infrequently reported, snakes may be predominant nest predators (Stake et al. 2005. J. Herpetol 39:215–222; Thompson III and Burhans 2003. J. Wildl. Manage. 67:408–416). On 10 July 2013 at ca. 1100 h we observed a *Thamnophis sirtalis dorsalis* predating an *Empidonax traillii extimus* (Southwestern Willow Flycatcher) nest with two nestlings near San Marcial, Socorro Co., New Mexico, USA. The *T. s. dorsalis* was anchored posteriorly ca. 7.6 cm below the nest, with the anterior third of its body hanging vertically in the process of ingesting a 13-day-old nestling head first. Given the placement of its body, it is likely the *T. s. dorsalis* predated the nest from below, possibly the best way to approach the nest given typical nestling behavior (positioned in or on the edge of the nest to detect potential predators) of *E. t. extimus* nestlings at this stage of their development (Paxton and Owen 2002. An Aging Guide for Willow Flycatcher Nestlings. U.S. Geological Survey. 18 pp.). Upon approach the snake released the nestling, which was ingested to the cloaca, and retreated into the Rio Grande. The nest was located 3 m above the ground in a 5-m-tall, live *Tamarix* sp. (saltcedar). *Thamnophis sirtalis* is known to predate passerine nests (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Books, Washington D.C. 668 pp). To our knowledge, this is the first report of Southwestern Willow Flycatcher nest predation by *T. s. dorsalis*. Research was conducted under United States Fish and Wildlife Service Permit TE819475-3.

SHAUN T. ROOT (e-mail: sroot@usbr.gov), **DUREL CARSTENSEN**, **DAVE MOORE**, **DARRELL AHLERS**, Bureau of Reclamation, Fisheries and Wildlife Group, PO Box 25007, Denver Colorado 80225, USA.

***THAMNOPHIS SIRTALIS PARIETALIS* (Red-sided Gartersnake). DIET AND ACCIDENTAL MORTALITY.** Snakes occasionally die while attempting to consume prey. For example, an *Agkistrodon contortrix* (Copperhead) apparently died after ingesting the head of a *Corvus ossifragus* (Fish Crow); the bird's beak penetrated through the skin of the snake (Beane et al. 2013. Herpetol. Rev. 44:150–151). Likely the death of a *Pituophis catenifer* (Gophersnake) in New Mexico occurred following consumption of an *Athene cunicularia* (Burrowing Owl; Painter et al. 2012. Herpetol. Rev. 43:152). Moreover, semi-aquatic snakes, such as *Agkistrodon piscivorus* (Cottonmouth) and *Nerodia sipedon* (Northern Watersnake), have died from complications related to the spines and fins of ingested fish (Allen and Swindell 1948. Cottonmouth Moccasin of Florida. Herpetologica 4:1st suppl.; Stafford 1952. Copeia 1952:193).

FIG. 1. A *Thamnophis sirtalis parietalis* that died after consuming a *Sternella neglecta* (Western Meadowlark) in central Nebraska. The single puncture hole is visible and located in the swollen area adjacent to the meadowlark skull.

On 23 June 2012, we discovered a gravid female *T. s. parietalis* (SVL = 590 mm) dead along the edge of a small pond in the flood plain of the Platte River in Hall County, Nebraska (40.7873°N, 98.465°W; datum WGS84). We observed the lower mandible of a *Sternella neglecta* (Western Meadowlark) protruding from one exit hole in the snake. We determined death was caused by the beak puncturing through both the digestive system and skin about 200 mm from the tip of the snake's head (Fig. 1). The meadowlark was consumed head first based on the direction of the beak, and we suspect the lower mandible eventually separated from the cranium causing the fatal puncture. The snake and skull of the meadowlark are deposited in the natural history collections at the Sternberg Museum of Natural History, Fort Hays State University, Hays, Kansas (FHSM 16537). *Thamnophis sirtalis* is known to eat a number of bird species but *S. neglecta* has not previously been documented as a prey item (Ernst and Ernst 2004. Snakes of the United States and Canada. Smithsonian Institution Press, Washington D.C. 680 pp.).

CHASE T. SVOBODA, Department of Biology, University of Nebraska at Kearney, Kearney, Nebraska 68849, USA; **GREG D. WRIGHT**, The Crane Trust, 6611 W. Whooping Crane Drive, Wood River, Nebraska 68883, USA; **JENNIFER D. FRISCH** and **KEITH GELUSO** (e-mail: gelusok1@unk.edu), Department of Biology, University of Nebraska at Kearney, Kearney, Nebraska 68849, USA.

***THAMNOPHIS SIRTALIS SIRTALIS* (Eastern Gartersnake). DIET.** *Thamnophis s. sirtalis* is a generalist feeder and has been known to consume salamanders of the genus *Plethodon* including *P. albagula*, *P. cinereus*, *P. cylindraceus*, *P. dunni*, *P. glutinosus*, and *P. idahoensis* (Ernst and Ernst 2003. Snakes of the United States and Canada. Smithsonian Institution Press, Washington, DC. 668 pp.; Konbalinka and Trauth 2003. Herpetol. Rev. 34:378). On 19 November 2013, an adult female *T. s. sirtalis* (SVL = 35 cm; total length = 46 cm; 17.35 g) was captured in a trap array located on the Camp Shelby Joint Forces Training Center, Forrest Co., Mississippi, USA. As the snake was being handled to morphometric data, it regurgitated a *P. mississippi*. The entire range of *P. mississippi* is within the range of *T. sirtalis* (Conant and Collins 1998. A Field Guide to Reptiles and Amphibians of Eastern and Central North America. 3rd ed., expanded. Houghton Mifflin Co., Boston, Massachusetts. 616 pp.). It is possible that the *P. mississippi* was consumed in the trap, and therefore it is unknown how frequently *T. sirtalis* will take this species as prey under natural circumstances. To the best of our knowledge this is the first documented occurrence of *P. mississippi* in the diet of *T. s. sirtalis*.

***TRIMORPHODON PAUCIMACULATUS* (Sinaloan Lyresnake). DIET.** Little is known about the natural history of *Trimorphodon paucimaculatus*, but it is thought to consume lizards, rodents, birds, and bats from rocky crevices and tree hollows like other lyresnakes (Scott and McDiarmid 1984. Cat. Amer. Amphib. Rept. 352:1–2; García and Ceballos 1994. Field Guide to the Reptiles and Amphibians of the Jalisco Coast, Mexico. Fundación Ecológica de Cuixmala, A.C. UNAM, D.F. 184 pp.). Here we document a new avian species in the diet of *T. paucimaculatus*.

On 15 July 2013, at 0100 h, a female *T. paucimaculatus* (SVL = 905 mm; tail length = 145 mm) was found dead on road at Las Varas–Chacala road, Municipality of Compostela, Nayarit, México (21.163935°N, 105.211336°W, datum WGS84; elev. 39 m). The habitat was tropical deciduous forest. We dissected the snake and found a partially digested *Icterus wagleri* (Black-vented Oriole) ingested head first (Howell and Webb 1995. Guide to the Birds of Mexico and Northern Central America. Oxford Univ. Press, New York. 851 pp.). Additionally, an unidentified nematode parasite was found in the snake's stomach. The snake and stomach contents were deposited in the vertebrate collection at Universidad Autónoma de Aguascalientes (UAA-CV-R265).

FIG. 1. *Trimorphodon paucimaculatus* that had consumed an *Icterus wagleri* (Black-vented Oriole) in Nayarit, México.

***UROTHECA GUENTHERI* (Striped Glasstail). ANTIPREDATOR DEFENSE.** *Urotheca* is a genus of poorly known terrestrial snakes that can be found in wet and rain forests of Central and South America (Savage 2002. The Amphibians and Reptiles of Costa Rica: A Herpetofauna between Two Continents, between Two Seas. Univ. Chicago Press, Illinois. 934 pp.). Most species in this genus are drab-colored shades of brown, likely providing crypsis among forest floor leaf litter. However, a few species are banded, presumably mimicking sympatric coral snake species (Savage and Crother 1989. Zool. J. Linn. Soc. 95:335–362). Although dorsally drab, *U. guentheri* is brightly colored orange to red ventrally. These high contrast colors may serve as anti-predator "flash" colors. Snakes in this genus have long tails (> 33% total length), that are very fragile (Solórzano 2004. Snakes of Costa Rica. INBio, Costa Rica. 792 pp.). Tails do not regenerate, but may fracture successively closer to the cloaca providing multiple escape opportunities over time (Savage, *op. cit.*). Tail waving may be a mechanism for anti-predator defense (Greene 1987. Snakes: The Evolution of Mystery in Nature. Univ. of California Press, Berkeley, California. 365 pp.), and Savage (*op. cit.*) suggests that tail cleavage is common in this genus, with frequencies above 50% of sampled populations. Herein I report behaviors that may further enhance the effectiveness of this anti-predator strategy.

FIG. 1. Reflexively coiled tail fragment of *Urotheca guentheri* pressing a sharp vertebral element into the skin of the author's left thumb.

On 21 June 2012 at 1320 h we observed an adult male *U. guentheri* on a trail in primary forest within the Monteverde Cloud Forest Preserve, Costa Rica (approx. 10.3001°N, 84.7474°E, datum WGS84; elev. ~1000 m). While handling the snake with minimal force, the tail broke ~3 cm posterior to the cloaca. Upon breakage, the snake began to roll its body in an apparent attempt to escape my grasp. Simultaneously, the detached tail began to writhe, and the bright ventral color was a potent visual stimulus. When I released the snake it ceased rolling and began pressing its head low and attempting to burrow under leaf litter. This behavior reduced the visual stimulus provided by the snake's venter, while the tail continued to flash bright orange as it thrashed in the leaf litter.

In addition to the effect of coloration, the separated tail fragment was able to coil around my finger when I picked it up from the leaf litter (Fig. 1). This behavior did not seem indicative of simple bilateral flexion. Either there was a bias so that the fragment flexed more forcibly to one side, or possibly a reflex action integrated in the remnant spinal cord was able to respond to a grasping stimulus and flex towards the side of tactile stimulus. Furthermore, after coiling around my finger, the proximal end of the tail fragment pressed forcibly against my hand. The protruding vertebral element was sharp and had a startling effect. While the snake was in my grasp, the exposed vertebral column of the remaining tail was also pressed into my skin in a comparable fashion. Similar tail-pressing behaviors have been noted in *Contia tenuis* (Sharp-tailed Snake), *Farancia* spp. (mud and rainbow snakes), and *Carphophis* spp. (wormsnakes). However, in these species it is the hardened tip of an intact tail that is used as a lancet as opposed to a vertebral element. The tail musculature surrounding the cleavage zone of the snake's remaining tail contracted, presumably to staunch bleeding. But, an additional consequence was the exaggerated exposure of the vertebral element.

Savage and Crother (1989) suggest that the tails of *Urotheca* species separate between vertebral centra. However, a fracture plane within, rather than between vertebrae has also been proposed (Wilson 1968. J. Herpetol. 1:93–94). Although I did not examine the tail fragment anatomically, the sharpness of the vertebral element may suggest a pointed or diagonal fracture plane within the centra. Further observations on the osteology and behavior of this, and other *Urotheca* species may reveal this behavior to be widespread within the genus, and shed light on the anatomical details of this novel defense strategy.

I thank Rebecca Cossel for her keen eyes in the field; Geiner Alvarado Huertas for GIS assistance; Christian Mena and Sergio Vargas for logistical support, and sharing video footage of the encounter.

***XENOPELTIS UNICOLOR* (Asian Sunbeam Snake). DIET.** Prey of *Xenopeltis unicolor* include frogs, lizards, snakes, small mammals, birds, and even reptilian eggs (Rooij 1917. The Reptiles of the Indo-Australian Archipelago, vol. II. Ophidia. E. J. Brill, Leiden, Holland. 334 pp.; Bergman 1955. Zool. Mededelingen, XXXIII, No. 22:209–225; Martins and Rosa 2012. Taprobanica 4:48–51). Small skinks and snakes are possibly the most common species in the snake's diet and *X. unicolor* possesses specialized tooth morphology for handling lizard prey. On 13 March 2013 at 1945 h, in the northeastern part of Phi Phi Don, the largest island of Phi Phi Archipelago, Andaman Sea, Thailand (7.770845°N, 98.767326°E; datum WGS84), I discovered an adult *Xenopeltis unicolor* coiled around a live adult male *Kaloula pulchra* near a burrow on the pond shore in an area of secondary tropical forest. The frog may have been attacked and constricted on the pond's shore where numerous male *K. pulchra* congregate for breeding. The snake continued to constrict the prey for 10 min, during which the frog produced a creaking sound (Fig. 1). Upon capture, the snake released the frog, which was alive and appeared undamaged.

FIG. 1. An adult *Xenopeltis unicolor* found preying on a *Kaloula pulchra* on Phi Phi Don island, Andaman Sea, Thailand.

Reptiles and Amphibians of Australia, 7th Edition

Harold G. Cogger. 2014. CSIRO Publishing, Collingwood, Melbourne, Australia (www.publish.csiro.au). xxx + 1033 pp. Hardcover. AU$150.00 (approx. US $140.00). ISBN 9780643100350.

BRETT A. GOODMAN
School of Earth & Environmental Sciences, University of Adelaide, Adelaide, South Australia, Australia 5005
e-mail: brett.goodman@adelaide.edu.au

The herpetofauna of Australia is one of the most diverse anywhere in the world. As such, a reference work that provides descriptions and dichotomous keys of all known reptile and frog species represents a significant contribution. The most recent edition of Hal Cogger's long awaited *Reptiles and Amphibians of Australia* updates Australia's longest standing, one-stop reference for all currently described herpetofauna. So well known and regarded is Hal Cogger's book that it is often referred to simply as "Cogger" or even "The Bible." Now in its 7th edition, the latest version represents a substantial increase in content since the release of the 6th edition (2000) 14 years ago. Indeed, so long is the interval between editions that used copies of the 6th edition frequently command high prices online (e.g., eBay US $500–800).

There is a significant increase in the number of new species included in the 7th edition, with 168 new reptile and frog species, in addition to a number of useful format changes. In the almost 40 years since the first edition, the documented diversity of Australia's reptile and frog species has almost doubled, growing steadily from 664 species (Cogger 1975) to 703 species (Cogger 1979) to 830 species (Cogger 1983) to 865 species (Cogger 1986) to 951 species (Cogger 1992) to 990 species (Cogger 1994) to 1004 species (Cogger 1996) to 1050 species (Cogger 2000) and finally to 1218 species (Cogger 2014). A new feature of the introduction is a table of all described species of reptiles and frogs by state/territory and bioregion (a total of 15 bioregions) within the Australian continent, including major island provinces (Lord Howe, Norfolk, Cocos [Keeling], and Christmas islands). A page number provides quick access to each species description and corresponding distribution map, facilitating the inclusion or exclusion of candidate species on the basis of geography. An additional change is the shift to a single text column for the species descriptions, bringing the format in line with that of the introduction and generic descriptions. Also new and appropriate to both the "biblical" status and size of the book is the inclusion of a ribbon place mark. An index of species common names in addition to one of solely scientific names is also very handy.

The introduction moves away from the task of the identification of reptile and frog species and includes discussion and maps highlighting biodiversity and conservation "hotspots" for herpetofauna across Australia. Areas with high species diversity are clearly indicated via a color-coded scale for all taxa. Individual biodiversity maps are provided for frogs, lizards and snakes. Hylid frogs and southern frogs (Leptodactylidae) are also mapped separately, highlighting differences in the hotspots of the two groups. There is also a philosophical discussion on conserving phylogenetic biodiversity and the value of one species over another—the fundamental issue of whether conservation efforts should be focused on the preservation of a single taxon of a speciose lineage as opposed to the single representative of a monotypic lineage (e.g., *Ctenotus* with approximately 103 species vs. the monotypic *Gnypetoscincus*).

A consistent feature in all editions of *Reptiles and Amphibians of Australia* is a section on how to locate specimens for photography and/or collection and research. This section provides detailed approaches and equipment for collection and sampling, with a brief section on transportation of live specimens and the correct methods for euthanasia and the preservation and fixation of specimens. There is also a section on introduced reptile and frog species and their impact on species on the mainland and island territories. Fittingly, the final part of the introduction deals with the most recent snakebite and first aid treatment.

As in previous editions, the identification keys for each genus are supported by line drawings illustrating the scales, scutes, and shields that are most relevant to the distinguishing features of each group. A helpful addition to the 7th edition is the use of colored keys to define those features most likely to distinguish a species. Each species is accompanied by its own species description and distribution map. Although subspecies are not defined *per se*, it is nice to see they are at least listed with a description of their known distribution. There has been considerable effort to include most new taxonomic references (through December 2012), with some of the more recent ones included in the addenda.

Species distribution maps often receive critical attention given the influence they can have on reliably identifying species. As Cogger points out (pp. 5–7) the informed user of this book needs to understand how to interpret the range maps provided. There are many approaches available for delineating species distributions. The most commonly used is the convex polygon, which uses the peripheral points in a set of records to estimate species boundaries. This approach does not consider discontinuities within the range and may overestimate distributional areas, particularly where there are large areas of unsuitable habitat or where there are isolated records outside the main distributional

range. Minimum polygon methods, on the other hand, work well when there are many distribution records, but may underestimate ranges when data are insufficient. The maps provided reflect the author's integration of a huge number of museum and literature records and a lifetime of familiarity with the Australian herpetofauna.

For any identification guide photographs of typical examples of species often provide the quickest way to successfully determine a specimen's identity. Unfortunately, the latest edition of *Reptiles and Amphibians of Australia* provides fewer color illustrations than the previous editions. The members of the genus *Ctenotus*—Australia's most diverse vertebrate genus—are provided with a color image in fewer than 60% of cases. While some may argue that this is a minor issue due to the morphological similarity of species within genera such as *Ctenotus*, it is always helpful having more photographic examples to work from. While most images included are of reasonable quality, many appear somewhat over-exposed, particularly those reproduced from previous editions. The use of poor quality photos seems avoidable given the number of competent herpetological and wildlife photographers who would have freely provided high quality images. More than likely, the judicious use of color images appears to have been an effort to maintain a reasonable price and size of the work given its scope. The images provided have been selected to demonstrate the range of color patterns and forms within a particular group and the type of habitats they occupy, with emphasis on the use of images depicting animals in their natural surroundings.

Casually thumbing through a work may not be especially informative—the real test of how well it performs under field conditions. To this end, my first real opportunity to test the latest edition of "Cogger" was on a recent field trip targeting skinks in the Shark Bay area of Western Australia. This location is known for its high scincid diversity, with a particularly high diversity of cryptozoic fossorial species of the genus *Lerista*, in addition to a large suite of surface active species. Here *Reptiles and Amphibians of Australia* really came into its own, with the keys for *Lerista* proving invaluable for distinguishing among the several quite-similar co-occurring congeners, and amply justifying the effort to bring this 3 kg field guide as carry-on luggage!

For any volume of this size, obtaining suitable proofing at the review stage is critical to eliminate obvious errors that can detract from the reader's confidence in the material presented. Unfortunately, the latest issue of the *Reptiles and Amphibians of Australia* has a fair number of obvious and annoying errors. While unproductive to list here, some typical errors include incorrectly labeled source localities for the photographs of specimens (e.g., *Anepischetosia maccoyi*; p. 414) and distribution maps that clearly differ from the in-text description of the species' distribution (e.g., *Lerista edwardsae*; p. 602).

The 14 years since the release of the 6th edition have seen the publication of several useful field guide-sized volumes for reptile and frog identification, which effectively filled the void left by the absence of an up-to-date edition of "Cogger." Most notable has been *A Complete Guide to Reptiles of Australia* (Wilson and Swan 2003). This work provides descriptions and high quality photographic plates, without dichotomous keys, and is now in its 4th revised edition (Wilson and Swan 2013). The identification of Australia's frog fauna has been given a significant boost with the recent release of *Tadpoles and Frogs of Australia* (Anstis 2013), which provides a comprehensive treatment of all known species and their larvae. In addition, several reptile and frog identification apps for both iPhone and Android (e.g., *Frogs Field Guide* by the Australia Museum) have been released. If and when *Reptiles and Amphibians of Australia* will become available in this format is currently unknown.

There is little doubt that producing the 7th edition of *Reptiles and Amphibians of Australia* has been a monumental challenge. Since the publication of the 6th edition there has been a change of publisher (from Reed publishing to CSIRO) and presumably, the associated copyright issues. Hal Cogger's initial motivation for the book was to provide the kind of work he would have liked to have had access to when in high school or at university. In the preface to the current edition he notes that over time the increasing size and cost of the book has tended to limit its access to the general reader and to people with a more general interest in natural history. Although its size may exclude it as an easily portable field guide, there is little doubt that *Reptiles and Amphibians of Australia* continues to promote awareness and appreciation of the national and global significance of Australia's herpetofauna and that it meets or exceeds the author's primary aim "to provide the means to identify the majority of the reptiles and frogs found in continental Australia and Tasmania" (p. xxvii). Now, more than ever, *Reptiles and Amphibians of Australia* represents a worthy addition to the library of anyone interested in Australian herpetology.

A Field Guide to the Snakes of Costa Rica

Gregory J. McConnell. 2014. Edition Chimaira, Frankfurt am Main, Germany (www.chimaira.de). Hardcover. 233 pp. 39.80 Euro (approximately US $53.40). ISBN 978-3-89973-431-7.

CESAR L. BARRIO-AMORÓS
Instituto de Biodiversidad Tropical (IBT), Apartado Postal 220-8000, Pérez Zeledón, San Isidro del General, 11901, Costa Rica
e-mail: cesarlba@yahoo.com

After being in touch with the editor and providing several photographs for use in this book, I was very curious to see how a new book on Costa Rican snakes would stack-up against the masterworks on the topic by Jay Savage (2002) and Alejandro Solórzano (2004). My expectations were probably too high, but the final result left me disappointed.

The book starts with acknowledgments and a short introduction by the author explaining the gestation of the book. There is no preface or back cover comments by noted herpetologists, as are often seen in books such as this. Unfortunately, there is also almost no introduction to the country, only a political map and no more than two paragraphs about the complex geography of Costa Rica, which is so important for understanding patterns of distribution. Fortunately, Savage (2002) in his encyclopedic volume provides this information, as does Solórzano (2004), although in a more limited way. The introduction about snakes is more in-depth, and covers the general biology and morphology of ophidians. There are five taxonomic chapters, one about Anomalepidae [sic], Typhlopidae and Leptotyphlopidae, another about Boidae, Loxocemidae and Ungaliophiidae, one more about Colubridae (sensu lato), another about Elapidae, and a last one about Viperidae. The final chapter is about snakebite and its treatment. The book continues with the distribution map section, with small schematic but clear maps, and a list of species with "original identifications" (i.e., current names with relevant authorship given) and allocations to subfamily. A far too short literature section closes the volume.

The strength of the book is that it has a great collection of photographs and can certainly be used as a visual catalogue. Herp fanatics and herpetologists, as well as naturalists in general, are always appreciative of good pictures, and this book has them. I also enjoyed the small collection of drawings by Claudia Hahn (see those of *Ninia celata*, p.101, *Rhadinaea pulveriventris*, p. 112, *Thammophis marcianus*, p. 126, *Trimetopon gracile*, p. 127, and *T. simile*, p. 128), some of which remind me of the classic plates of the pre-photographic age. I welcome such a beautiful set of images, and will consult them often.

What I will not consult is the text, which contributes nothing new relative to Savage (2002) and Solórzano (2004). The maps and text summarize the information in these two volumes and do not seem to reflect any new or interesting findings, or if such data are present they are not noted as such. There are a good number of mistakes and much misleading information in McConnell's book. I document some instances below, but also take the opportunity to comment on Savage's (2002) and Solórzano's (2004) works when relevant, and add some new information derived from recent papers not treated by McConnell.

To say that Costa Rica is in the southern part of North America (p. 12) is incorrect; along with Panama, Nicaragua, Honduras, El Salvador, Guatemala, Belize, and Mexico as far north as the Isthmus of Tehuantepec, it is in Mesoamerica, a macro-region that is widely recognized geographically, ecologically, and anthropologically. The reference to taxonomists as either "splitters" and "lumpers" (p. 13) is an outmoded notion that has been superseded as modern workers adopt an integrative taxonomy approach that combine as many possible methods and data sources to make more objective decisions (see Padial et al. 2010). McConnell states that "studies of the structures of the reproductive organs of male snakes (hemipenis) have further contributed to snake taxonomy, but this author [McConnell] questions the validity of the adornments of these as taxonomic features for obvious reasons (consider the differences among the human penis)." Such a view seems misguided in light of the extensive works by Dowling and Savage (1960), Zaher (1999), and Myers (2011), just to name a few.

The author makes the statement that "many venomous snakes of both families (referring to Elapidae and Viperidae), possess dark heads or dark stripes over the venom glands, possibly to prevent the denaturation of the numerous proteins and enzymes from exposure to the sun's ultraviolet rays" (p. 19). Although this theory was proposed long ago (Pough et al. 1978), this key reference is not cited and in Costa Rica, most venomous species have mostly light brown to gray heads (black only in *Lachesis melanocephala* and *Hydrophis platurus*, and generally dark gray in *Porthidium nasutum*, like the rest of the body), or are green, with very thin dark stripes. There is even one species (*Porthidium volcanicum*) that has white stripes over the gland area. Furthermore, in the case of elapids (coral snakes), the black ring on the rear of the head often does not cover the venom glands.

McConnell refers to and bemoans the "trash can" concept of the family Colubridae (p. 18), which was true until recently, but modern molecular methods have partitioned the Colubroidea to yield monophyletic families within the old Colubridae (e.g., Hedges et al. 2009; Zaher et al. 2009). These papers support the recognition of the subfamilies Xenodontinae and Dipsadinae within the family Dipsadidae Bonaparte, 1838, which currently includes many more species than the reduced Colubridae now recognized. Additional new interpretations on the family Dipsadidae have been published by Vidal et al (2010) and Grazziotin et al. (2012), and the phylogeny of all Squamata was recently published by Pyron et al. (2013). Although McConnell cites both Zaher et al. (2009) and Vidal et al. (2010) he does not embrace the new taxonomy that challenges the "trash can" concept.

Neither is the current taxonomy of anurans employed. Two species named in the introduction (p. 19) are both outdated. *Bufo marinus* changed to *Chaunus* based on Frost et al. (2006), and is now referred to *Rhinella* (after Chaparro et al. 2007). *Leptodactylus pentadactylus* is a South American species. The Costa Rican species in the *pentadactylus* group is *L. savagei* (Heyer 2005).

Other issues involving problems with names include the mention of Texan leptotyphlopids as *Typhlops* (p. 23), extremely limited information on certain taxa, including *Leptodrymus pulcherrimus*, *Nothopsis rugosus*, and the genus *Geophis*, and numerous out-of-date or incorrect applications of names.

Chironius carinatus is no longer a Costa Rican species; the subspecies *C. c. flavopictus* was raised to specific level by Hollis (2006). *Dendrophidion vinitor* is no longer considered to occur in Costa Rica, rather the Caribbean former *vinitor* is now known as *D. apharocybe*, and the Pacific "*vinitor*" is now *D. crybelum* Cadle (2012). The "*D. vinitor*" that appears in figures 114 and 116 is *D. crybellum* (based on biogeography), and the "*vinitor*" from Rio San Juan, Nicaragua in figure 113 is *D. apharocybe*. In this case the author probably had no time to add the new data, but he did comment on an observation of *Ungaliophis* made in 2012 and I was in touch with the editor (regarding photographs), who was open to changes as late as the last quarter of 2013.

The discussion of *Dipsas* is confusing. First the author notes three species, then only two, but in the photographic section and distribution map section, there are again three species depicted. Savage and Bolaños (2009) consider three species, *D. articulata, D. bicolor,* and *D. tenuissima*. Regarding *Drymarchon*, McConnell states that "*D. corais* was formerly known as the subspecies *D. melanurus corais*" (actually it was *D. corais melanurus*), and the correct name for the *Drymarchon* inhabiting Costa Rica is *D. melanurus* (Savage and Bolaños 2009). He also notes that many authors split the genus into four species (e.g., Wüster et al. 2001), but does not follow this himself. Regarding *Enulius*, McConnell follows Savage's (2002) point of view that *sclateri* is not *Enuliophis* (after McCranie and Villa 1993), and that the genus has two species in Costa Rica. Solórzano (2004) on the other hand, believes the description of the new genus is convincing and uses *Enuliophis*. This is a matter of opinion, but McConnell is in error in stating that is was *E. flavitorques* rather than *E. sclateri* that had been considered *Enuliophis*.

Erythrolamprus epinephelus has been treated incorrectly by several authors as "*epinephalus*" (including Savage [2002] and Solórzano [2004], and consequently McConnell, but not Köhler [2003]). Savage and Bolaños (2009) explain this error.

Imantodes is a genus represented by three species in Costa Rica. While *I. cenchoa* is generally the most common species and is widespread within the country (except in the drier parts), *I. gemnistratus* is very similar but occurs in more xeric areas and is mostly parapatric with respect to the previous species. In cases of such similarity among close species, a better explanation of their differences would be appreciated. In the case of *I. inornatus* the author states that it is "limited to the Caribbean slope," however, figure 15 depicts a specimen from Quepos (Central Pacific), and even though the locality data were not solicited from the photographer (myself), if one is familiar with the color pattern of Caribbean and Pacific *Agalychnis callidryas* (also in the photo), one can verify that the picture was taken on the Pacific slope. The distribution map of *I. inornatus* fails to reveal its presence (documented by Savage [2002] and Solórzano [2004]) in the southwestern Pacific area (only one place on the Osa Peninsula is plotted).

Though the information would not have arrived in time for the author to incorporate, a recent paper by Ruane et al. (2014) has changed the whole scenario for milksnakes. In Costa Rica, two subspecies of *Lampropeltis triangulum* were known, *L. t. gaigeae*, the black milksnake, and *L. t. stuarti*, a tricolor banded milksnake. Now, two species are known, *L. abnorma* (the old *stuarti*), and *L. micropholis* (the old *gaigeae*).

Leptodeira is a genus with four species in Costa Rica. *L. nigrofasciata* and *L. rubricata* are quite well defined (Savage 2002), but *L. annulata* (one of the most widespread species in the Neotropics) needs further study. Earlier authors made the attempt to distinguish this species from the extremely similar *L. septentrionalis*, but unconvincingly: Solórzano reported a lower ventral count in *annulata*, whereas Savage cited differences in head color pattern, which I have found to be inconsistent, as in my experience *L. annulata* is one of the most variable species known. McConnell does not even attempt to differentiate the two species, but I did find his mention of a bite he suffered from *L. septentrionalis* interesting. Such cases deserve publication in specialized journals. An important paper about evolution in *Leptodeira* is missing in the reference section. Daza et al. (2009) showed that the recognized taxa do not represent natural groupings. The most striking results are that *L. nigrofasciata* should be recognized as a different genus, that *L. rubricata* may be a synonym of *L. annulata rhombifera*, and that the *annulata-septentrionalis* complex is polyphyletic.

Regarding *Leptophis*, five species are known to occur in Costa Rica, of which only four are mentioned by McConnell (the missing one is *L. riveti*, although two pictures of the species appear in the plate section). It is strange that Savage (2002) does not compare *Leptophis nebulosus* with *L. riveti*, which to me seem to be potentially synonymous. The only differences are the longer postocular stripe in *riveti*, and a higher count of ventrals in *nebulosus*. This is not enough for me to distinguish among species alone, and can be due to intraspecific variation.

The genus *Pseustes* is no longer valid, and the Central American representative, *P. poecilonotus* is now in the genus *Phrynonax* (Jadin et al. 2013). The genus *Trimorphodon* is represented in Costa Rica by one species, *T. quadruplex,* not *T. biscutatus*, as reported by McConnell (Devitt et al. 2008). *Tripanurgos compressus* has been placed in *Siphlophis* for some time (Zaher and Prudente 1999), based on hemipenial morphology, and in molecular studies *S. compressus* is embedded with *S. cervinus* (an Amazonian species; Vidal et al. 2010; Grazziotin et al. 2012; Pyron et al. 2013).

The only recent taxonomic change of which I was not aware and that this book brought to my attention, was the split of *Rhadinaea* and the resurrection of the genus *Rhadinella* Smith, 1941 for several species in the former genus, two of them in Costa Rica: *R. godmani* and *R. serperaster*. Unfortunately there is no mention of the source of this action in the book and I needed to dig (with the help of Victor Acosta) to find the relevant reference (Myers 2011).

Pelamis platurus is no longer in the genus *Pelamis*, but rather is embedded in *Hydrophis* (Sanders et al. 2012). McConnell states that a few specimens have been found in the Atlantic Ocean (in the Caribbean Sea near the Panama Canal Zone). Although *H. platurus* is present in the Caribbean, to my knowledge it has not yet been cited in Panama, but only in Colombia (Hernandez-Camacho et al. 2006). Further, recent studies (Solórzano 2011; Sheehy et al. 2012) have identified a pygmy yellow population in the Golfo Dulce. This is one of the most interesting recent discoveries about Costa Rican snakes, but is overlooked entirely in this book.

McConnell incorrectly states that *Agkistrodon* occurs as far south as southern South America! In fact it reaches its southern distribution in northwestern Costa Rica. The species in Costa Rica and neighboring countries (Nicaragua, Honduras), is now referred to as *A. howardgloydi*, having recently been raised from subspecific level under *A. bilineatus* (Porras et al. 2013). The author regards both *Porthidium nasutum* and *P. porrasi* as inhabiting the same area of the Peninsula de Osa. Actually, the "*nasutum*" from southwestern Costa Rica was subsequently described

as *P. porrasi*, and in Costa Rica *nasutum* is recognized only from the Caribbean (Lamar and Sasa 2003; Campbell and Lamar 2004).

As previously noted, the photographs are unquestionably the best part of the book, and credit for this must be given to the editor, Gerold Schipper, who searched for the best pictures of each species over a long period. I did not see a single photograph by the author himself. Figure 9 identifies *Mastigodryas melanolomus* as a *Dryadophis*. While some authors do use *Dryadophis* for this species, the most recent genetic data (Pyron et al. 2013) support the use *Mastigodryas*, as *melanolomus* is embedded within this genus. Indeed, McConnell confusingly uses *Mastigodryas* in the text and other photos. Also in the photographic section, *Ungaliophis panamensis* (correct in the text), is misspelled as *U. panamansis*.
